Rules of Bending, Bending the Rules: The Geometry of Electrical Conduit Bending in College and Workplace

Wolff-Michael Roth

Using cultural-historical activity theory as my framework, I report an empirical study of how electrician apprentices learn to bend electrical conduits in college and on the job. The requirements for doing well in the two locations are very different: exhibiting knowledge of trigonometry, on the one hand, and doing a good job that makes bending and subsequent pulling of wires practical. Formal trigonometry is the reference in the classroom, whereas rules of practice are the main references on the job. In each case, the practices orient themselves to the Canadian codebook, which provides a description that the inspector uses as his/her reference when checking for approval. However, the sharp differences between the two forms of practice and the contradictions arising from them are reintegrated into the stories that are constitutive of the community of practice. Implications are discussed with respect to the concept of “boundary crossing” through the lens of cultural-historical activity theory and its concepts for the development of the individual: subjectification, which describes the changes *within* an activity system (school, work) and personality, the changes the individual undergoes as s/he moves repeatedly *between* systems of activity.

1 Introduction – on activities and boundaries that separate them

The purpose of this study is to present empirical data on the mathematics electrician apprentices learn in their formal schooling and the very different mathematical practices they encounter in the everyday work on the job. I use the results to reflect on the relation

1
2
3
4
5 between the different mathematics in the process of developing an identity, or rather, in
6 developing personality. At issue in this paper, thereby, are the supposed boundaries
7 between two different activities: schooling and work. But do such boundaries exist and, if
8 so, how are these experienced? The following brief phenomenological investigation
9 sketches out a first answer.
10
11
12
13
14

15 Every day takes me through many very different kinds of activities making very
16 different kinds of demands in terms of mathematical competencies, at work (as researcher
17 of mathematical practices, statistician), at home (as producer of all fruits and vegetables we
18 need year round, chicken farmer, home renovator, beekeeper, cook), and in the community
19 (shopping, doing service work). Despite the variety of mathematical practices and concerns,
20 and despite the very different cultural-historical activity systems in which I am an acting
21 subject at the time, I never have a sense of crossing boundaries, of being somehow different.
22 Indeed, I have the sense of being the same person who *integrates* very different demands
23 and object/motives that define the different activities in which I am the subject.
24 Continuously becoming a subject in each of these fields, a process I denote by the term
25 *subjectification*, is part of my being and becoming a person, of my *personality*. I have been
26 able to observe very similar integrations as part of my ethnographic fieldwork on research
27 science and a range of workplaces. Yet there are theoretical approaches and research that
28 tell me that I ought to focus on the boundaries between these activities and understand any
29 transfer that occurs between them in terms of the category of boundary crossing.

50 *1.1 On boundaries and boundary crossing*

51 Since around the publication of *Cognition in Practice* (Lave, 1988), much has been
52 written about the differences between formal mathematics as taught in schools and colleges
53 and mathematics in a variety of work-related activities, including packaging goods in dairy
54 factories (Scribner, 1986), banking (Noss & Hoyles, 1996), selling candy in street markets
55 (Saxe, 1991), and hatching salmon (Roth, 2005). Studies show time and again that

5 regardless of level of instruction, practitioners – such as bookies with 0 to 11 years of
6 schooling (Schliemann & Acioly, 1989) – tend to be highly proficient in their day-to-day
7 practice. However, the ability to solve and the number of correct answers on school-like
8 problems often exhibit statistically significant relations with school instruction, even
9 though the latter does not generally influence the specific nature of chosen solution
10 approaches. There appear to be real boundaries between the kinds of practices between
11 school, on the one hand, and the everyday praxis of work and life, on the other hand.
12
13 Practitioners especially feel that those arriving on the job from formal schooling know very
14 little and have to begin by learning first what really matters on and to the job (Lee & Roth,
15 2004). At the same time, those with too much formal knowledge are often characterized in
16 the field as “too smart,” destined for some office job or a job where formal knowledge is
17 appreciated (Lee & Roth, 2006). It does not surprise, therefore, that there is a lot of
18 boundary and boundary crossing talk in recent scholarship on the transitions between
19 school and work (e.g., Tuomi-Gröhn & Engeström, 2003).

There are strong theoretical reasons from the philosophy of difference why the concept
of boundary crossing does not make sense, for each culture is not a self-identical entity but
already constitutes a *mêlée* of socio-cultural practices and spaces that are continually
hybridized into new forms of practices and spaces (Nancy, 1993). Rather than different
spaces and boundaries between them, we actually observe (a) a continuous hybridization of
cultural practices and identities and (b) an integration of contradictions within and
between practices and identities. Are there other ways of theorizing the different
mathematical practices that distinguish formal educational contexts – secondary schools,
vocational schools, universities – and the everyday work praxis? Indeed there are, one
being cultural-historical activity theory in its original formulation and the way it integrates
a person’s trajectories across multiple activities.

61 *1.2 Knot-worked object/motives constitute personality*

Cultural-historical activity theory allows us to think about what happens to an individual who participates within an activity over time and whose trajectories takes it through/across different activities in the course of a day, week, month or year (Leontjew, 1982). The category *activity* refers to the structure of a cultural-historical productive process that contributes to the maintenance and transformation of society as a whole by accomplishing one part of the total labor required (Roth & Lee, 2007). Activities are subject to cultural-historical change processes, in fact, they produce cultural and historical changes; and, with these, the subject of productive activity also comes to be changed on both a material plane (e.g., more skilled, economical, physically strengthened or burned out) and an ideal plane (e.g., consciousness, understanding, and discourse) (Marx & Engels, 1962; Vygotsky, 1989).

The analytic category of *subjectification* (Roth & Radford, 2011) brings together the idea of the cultural-historical subject as agent in the activity system and the idea of the subjectification process from philosophy of politics (Rancière, 1999). I understand subjectification to be a process by means of which the individual person continuously changes: as the productive *subject of labor*, the person becomes more knowledgeable and skilled and as the patient of activity, the person is *subject(ed) to* the activity and the societal relations that come with it. A person undergoes subjectification in each and every activity where s/he participates in the course of the day, week, or month.

Human individuals do not just take part in single activities but in fact participate in many activities on the same day, often in multiple activities simultaneously. However, the conscious object/motives that orient the different activities have different degrees of importance to the individual: from his/her perspective, there is a hierarchically organized knotwork of object/motives that intertwines the different activities (Leontjew, 1982). The knots are not the result of “the biological or mental forces of the subject, which lie within it, but are created in the system of relations that the subject enters” (p. 178). Thus, the hierarchical connections between object/motives “constitute the ‘knots’ for personality” (p.

1
2
3
4
5 197). The formation of the knots is a latent process, which results from the many
6
7 object/motives and from the nature of the societal relations that the subject entertains. In
8
9 this manner, “the knots and their hierarchies form the mysterious ‘center of personality’
10
11 that we call ‘I’” (p. 216). In other words, the personality is the singular knotwork of the
12
13 different collective object/motives that constitute society. The formation of the knotwork,
14
15 the process of knot-working, is the result of both an active process, such as when
16
17 individuals decide to enter and participate in specific activities (e.g., becoming a licensed
18
19 electrician), and latent process, based on the fact that there are already objective (economic
20
21 or exchange) relations that exist between the different activity systems.
22
23

24 With this framework in place, we can now appreciate the research on the differences of
25
26 cognition in formal schooling and workplace. In each of these activities, an individual
27
28 undergoes the process of subjectification, becoming (developing as a student in one and as
29
30 a worker in the other). However, rather than focusing on the boundaries, Leontjew asks us
31
32 to think about how the person actually comes to weave together his/her involvements in
33
34 different activities and prioritizes the different object/motives; or, rather, he asks us how
35
36 these object/motives come to be knotted into a network that constitutes personality. My
37
38 research shows that for practitioners, the object/motives of formal schooling tend to have
39
40 very low priority; and this fact comes to be an integral part of the personality that they
41
42 develop. The same approach allows us to understand why some workers appear to be much
43
44 less motivated than others, which is actually not at all a matter of motivation but of
45
46 different hierarchies of object/motives that constitute the personality (Lee & Roth, 2007).
47
48
49
50

51 **2 Research context**

52
53 Over more than a decade, my research team has conducted ethnographic studies of
54
55 knowing and learning mathematics (and science) in a variety of settings: undergraduate
56
57 and graduate science students during laboratory and field internships, fish culturists,
58
59 electricians, mariners, dentists, environmentalists, and teachers. In each of these contexts,
60
61
62
63
64
65

1
2
3
4
5 we have drawn on a particular combination of methods (Roth, in press) that brings together
6
7 more traditional participant observation with *apprenticeship* as field method (Coy, 1989),
8
9 where the researcher signs up as a helper or, in the case of the electricians, completes, a
10
11 trade apprenticeship program. In all cases, we also use an “interactive ethnographic design”
12
13 where the researcher in the field continually debriefs with another researcher. In addition,
14
15 we meet regularly for interaction analysis sessions, whereby the entire research team and
16
17 other interested individuals engage in collective analysis and discussions of interpretations.
18
19

20 In this particular study, one of my graduate students (R. Racca) enrolled in a four-year
21
22 training program at a local college to become a licensed electrician (*Trade Interprovincial*
23
24 *Qualification*) and worked as apprentice for four local companies. Throughout the program,
25
26 he kept field notes, shot photographs, and photocopied pertinent documents; he also
27
28 conducted interviews. To provide further depth to the data, I also have monitored various
29
30 online forums, in which electricians from around the world discuss a variety of problems
31
32 arising from their work, including conduit bending. I studied code and practice and have
33
34 personal experience of designing a complete wiring system, followed by observing the
35
36 electrician hired to complete the job.
37
38

39 The college curriculum focuses on formal knowledge. Within the first month of the
40
41 program, students must master units on solving mathematical problems (problems
42
43 involving whole numbers, fractions, decimal fractions, ratios and proportions, percentages,
44
45 powers and roots, graphs, and geometry) and sections on science (properties of matter,
46
47 thermodynamics, mechanical physics). The curriculum also includes several shop units,
48
49 where students erect scaffolds and ladders, use specialized power tools, and cut, thread,
50
51 and bend (rigid) electric metallic conduit.
52
53

54 55 56 **3 The mathematics of conduit bending** 57

58 There are two very different fields of knowing that an apprentice encounters during
59
60 training, school, and work, held together by a third, the electrical code of Canada. In the
61
62

1
2
3
4
5 following subsections, I describe each of these fields and then articulate how electrical
6 apprentices knotwork them.
7
8
9

10 11 *3.1 Conduit bending – the electrical code* 12

13 For safety reasons, electrical wiring has to be shielded and grounded, which is achieved
14 by running it, where necessary, through electrical metal tubing (EMT) or electrical conduits
15 (Figure 1). The electrical code of Canada does not contain reference to mathematics but
16 specifies general rules for bending electrical metal tubing such as the minimum radius of
17 the turn – e.g., Rule 12-922(1) states “Where conductors are drawn into a raceway, the
18 radius of the curve to the centre line of any bend shall be not less than as shown in Table 7”
19 (CSA, 2003, p. 3). A table then specifies the minimum radius to the centre of the conduit for
20 a trade size ½ inch of conduit (16 mm) to be 4 inches (102 mm). The rule also specifies that
21 the bends have be made without undue distortion of the electrical metal tubing and without
22 injury to its inner or outer surfaces. The bends must be round and should be made with the
23 proper tool and may not be made by bending around some object such as a car bumper or a
24 tree (Knight, 2002). Rule 12-942 states that there cannot be more than a total of four 90°
25 bends. This code is the reference both in and to college and workplace practices.

42
43
44

45 *3.2 Conduit bending – in college (theory and hands-on)* 46

47 In college, the students intending to become electricians are taught conduit bending
48 theory. The students in our study were provided with conduit, benders, and a standard
49 textbook on the topic, *Electricians Guide to Conduit Bending* (Cox, 1982). Students are
50 required to study basic trigonometry: sine, cosine, tangent, cotangent, secant, and cosecant.
51 The textbook provides students with “magic circles” to remember how to calculate such
52 functions as the sine, cosine, and tangent (Figure 2). By placing a finger or thumb on one of
53 the letters, the device tells students the mathematical operation to conduct. Thus, for
54
55
56
57
58
59
60
61
62
63
64
65

example, to calculate the sine, the student places a finger on the “S,” leaving the other two letters open, with the “O” above the line and the “H” below the line, which translates into the mathematical operation $\sin(\Omega) = O/H$, where Ω is the desired angle (Figure 2). Equivalently, if the student wants to know the length of the hypotenuse given the sine and the opposite side, then s/he places the finger on the “H.” As a result, s/he calculates $H = O/\sin(\Omega)$. Common angles used are 10° , 22.5° , 30° , 45° , 60° , and 90° .

««««« Insert Figure 2 about here »»»»»

Students may be asked to produce an offset for the electrical metal tubing that takes the electrical wires around a 10-inch beam given an angle of 22.5° . The student uses the magic circle to calculate the required missing hypotenuse (Figure 3). Looking up the sine of 22.5° , the student can get the hypotenuse, which is, the length between the two bends to be

$$H = \frac{O}{S} = \frac{10}{\sin(22.5^\circ)} = \frac{10}{.3827} = 26.1. \quad (1)$$

That is, the student marks off on the conduit to be bent a distance of 26.1 inch. Because the conduit must be in one piece according to the code, the student also has to calculate where in the conduit the first bend has to lie, that is, how far away from the obstacle. Here, too, the textbook asks students to draw on one of the magic circles.

««««« Insert Figure 3 about here »»»»»

In their college course, therefore, the electrical apprentices carry out extensive calculations and measurements to determine angles, their positions on the tubing, and the distances between the angles. Once a student has calculated the distances, s/he uses measuring tape and bender to produce the tubing such that it properly bypasses the obstacle provided. Our fieldwork shows that in the case of an error, the tubing is discarded without any attempt in rectifying the bend. A reanalysis would be asked of the student to ascertain whether there was an error in calculation or measurement. The actual time spent on the task is immaterial in the course, because the only requirement in this self-paced unit is placed on getting the pipe correctly bent. During the research, many students in the

1
2
3
4
5 program struggled with the mathematics, which they, especially after working for a first
6
7 time as apprentice, tend to find entirely irrelevant to the work they do; and they tend to feel
8
9 “psyched out” by the examinations they have to take.

10
11 In their conduit bending class, those apprentices who begin with the college courses
12
13 also encounter for the first time a conduit bender (Figure 4). It is not just an unmarked tool,
14
15 such as a hammer, but a tool that includes different marks and representations, including,
16
17 on one side, angle measures and markers. On the reverse side, there are numbers
18
19 corresponding to each angle, which in fact are the cotangent values that correspond to the
20
21 angles. However, in the college classes, the students do not use these numbers but calculate
22
23 distances between the bends based on trigonometric calculations.
24
25

26 ««««« Insert Figure 4 about here »»»»»

27
28 A typical offset represented in Figure 3 involves two bends. The student marks off the
29
30 calculated distance between the two bends. The bender is placed on the tubing such that
31
32 the arrow (lower photo, Figure 4) points to the first mark on the tubing. Pushing on the
33
34 handle, the tubing is bent until it is parallel to the line on the tool corresponding to the
35
36 desired angle. The second bend is accomplished at the second mark in such a way that the
37
38 entire tubing remains in a plane, that is, rests flat on the floor.
39
40

41 Although the process of increasingly becoming a competent college student, that is, one
42
43 who passes the exams, subjectification also means going through particular experiences
44
45 with the formal knowledge that appears to have an existence in its own right, separate from
46
47 practical knowledge on the job. This is apparent in the following field note:
48
49

50 After getting 97% on the first year’s “Code” exam, I rejoin the ELT program, and I
51
52 suddenly find myself unable to write the ELT-E “Code” exam – unsure of how to
53
54 approach preparing for it. I spent two days going over the different sections of the
55
56 “Code” book that I have covered with the first years: I know that I know the material,
57
58 but something about how I know the material does not fit the framework of how the
59
60
61
62
63
64
65

1
2
3
4
5 ELT students work on “Code.” I keep “psyching myself out” as far as taking the ELT
6
7 “Code” exam. (Racca, January 1999)
8

9
10 Psyching oneself out over being successful on an upcoming exam and learning to cope with
11 the associated stress is as much part of becoming a college student as coming to know the
12 geometry of formal conduit bending. Even Racca, who, with a Bachelors degree in science
13 completed the college courses with greater ease and higher grades than others, psyching
14 himself out was integral to his college experience.
15
16
17
18
19
20
21

22 *3.3 Conduit bending – in the field*

23
24 In contrast to the classroom, conduit bending in the field does not use trigonometry but
25 implements a set of unwritten global rules:
26

- 27 – *two 90s*: do not exceed a total of 180° between any two pull points, as greater totals
28 would make pulling harder;
29
- 30 – *no dog legs*: the tubing must be bent such that it offsets while remaining in the same
31 plane;
32
- 33 – *shallow-is-mellow*: smaller angles are preferable to larger ones, as it makes pulling
34 easier;
35
- 36 – *looks count*: the tubing is to be laid such that it runs horizontally and vertically, as
37 long as possible, with a minimum number of couples [places where pipes join] and
38 identical offsets [horizontal displacement required for a pipe to get around an
39 obstacle] in parallel conduits; and
40
- 41 – *forgive or forget*: errors in bent tubing are corrected, rather than tubing abandoned
42 (cost!), because the tubing is “forgiving.”
43
44
45
46
47
48
49
50
51
52

53
54 These are rules of thumb that are adapted such that the electrical code is met, which is the
55 ultimate requirement as the installation is subject to inspection. For example, the practical
56 rule “two 90s” is more stringent than the code but makes the life of the electrician easier.
57
58 Some electricians feel that code “is 99% how it works, and 1% how it looks” and that they
59
60
61
62
63
64
65

1
2
3
4
5 “can bend a pipe to code but if [they] were try to bend a pipe pretty, it ain't a gonna
6
7 happen!” Adaptations are necessary, for on the job there are contingencies for laying
8
9 conduit that have not been apparent to architects and engineers designing the blueprints in
10
11 the electricians’ hands.
12

13 In our research, not a single electrician made reference to the textbook approach when
14
15 bending electrical conduit tubing. The most common is the “multiplier method,” which is
16
17 also described on the operating description that the toolmaker supplies (e.g., Greenlee
18
19 Textron, 1998). Electricians tend to know the multipliers for the most common angles used
20
21 in the trade and these are also marked off on the bender (Figure 4, top). Thus, to the set of
22
23 angles $\{10^\circ, 22.5^\circ, 30^\circ, 45^\circ, 60^\circ\}$ the corresponding set of multipliers is $\{5.76, 2.60, 2.00,$
24
25 $1.41, 1.15\}$. An electrician who wants to produce a 10-inch offset knows that the distance
26
27 between the two angles will have to be $d = 10'' * 2.60 = 26''$. Although some electricians in
28
29 our study knew of the multipliers needed to produce the location of the first bend, the
30
31 location was produced almost exclusively “by feel.” Experienced electricians placed the
32
33 second bend correctly; and in the exceptional case where the bend was not in a sufficiently
34
35 accurate position, minor adjustments to the overall length of the electrical metallic tubing
36
37 were made. My observations of plumbers at work show that such a qualitative approach
38
39 also is a characteristic of their geometrical practices at work. They tend not to use
40
41 measuring tape to mark off how much pipe to cut, but use some old piece of pipe that they
42
43 hold in the place to mark with their finger nail the required length and then, holding it to
44
45 the material, cut the required piece. If the length does not yield the required length to
46
47 produce a 90° angle with another pipe, then they cut off a piece until the required “looks,” a
48
49 more-or-less perfect 90° angle, is achieved.
50
51
52

53 Unbeknownst to most electricians, the multiplier method is based on cotangent and
54
55 cosecant. Thus, given an angle Ω and $\cotan(\Omega) = \text{adjacent/opposite}$, the adjacent = $\cotan(\Omega)$
56
57 * opposite. Here, the multiplier is the cotangent of the desired angle. Similarly, given that
58
59 $\text{cosec}(\Omega) = \text{hypotenuse/opposite}$, the hypotenuse = $\text{cosec}(\Omega) * \text{opposite}$. The multiplier
60
61
62
63
64
65

1
2
3
4
5 method is easy, as the electricians either remember them – more senior practitioners have
6 them more easily available than more junior members of the field – and some carry “cheat
7 sheets,” which contain the multipliers for different angles when these are not available on
8 the tool itself. Our fieldwork shows that the use of easily remembered multipliers is
9 particularly important for young workers: The electricians do not calculate but use the
10 means at hand (markings on the tool) to arrive at an accurate and failure-proof bend.
11
12
13
14
15
16

17 Apprentices learn the practice of conduit bending from journeymen and senior
18 apprentices. However, instruction seldom is direct. Rather, the apprentice follows orders
19 such as “do a 6-inch offset using 30 degree bends.” This forces the apprentice to do much of
20 the bending work, thereby coming to know the multipliers by heart. The journeymen and
21 senior apprentices generally do not explicate their choices but rather follow the rules of
22 thumb that they have learned in the course of their apprenticeship. Bending practices
23 thereby come to be reproduced; and few know the underlying reasons for particular
24 choices and practices. There is also a lot of story telling and story retelling, and these stories
25 embody cultural knowledge that is reproduced and transformed as they are “passed
26 around.”
27
28
29
30
31
32
33
34
35
36
37

38 Apprentices also begin to experiment on their own, while still working under the
39 supervision of a journeyman electrician. Ease of calculation and working under the
40 constraints of the actual worksite determines preferences the apprentice develops. The
41 selection of the angles then emerges from a number of contingencies, as exhibited in the
42 following field note in which the journeyman suggests what to do to install ½-inch electrical
43 conduit tubing that runs along steel trusses, including an offset bent. Asked by the
44 apprentice about how to do it, the journeyman suggested:
45
46
47
48
49
50
51
52

53 Ideally you want to use twenty-two-degree [sic] bends, 'cause they're the easiest to
54 pull wire through. But the multiplier for those bends is hard to remember and hard
55 to multiply by. Also, when you put in twenty-two-degree bends, you have to look at
56 the markings on the bender to see when you're there. When you work on scaffolding,
57
58
59
60
61
62
63
64
65

1
2
3
4
5 three floors up, you don't want to be bending down to check your markings. Instead
6
7 you want to put in thirty-degree bends: the multiplier is two, so you double the
8
9 depth of the offset, and you have the distance to mark between the bends. And when
10
11 the handle of the bender is straight up and down, the bend is thirty-degrees, and you
12
13 don't have to check the markings. Twenty-twos would be nice, thirties are easiest,
14
15 and never put in forty-fives: they're a bitch to pull wires through. (Racca et al. 2000,
16
17 p. 12)
18

19
20 This field note shows that 30° angles are chosen because the multiplier is easily
21
22 remembered, even though a 22.5° angle would make pulling the wire through the conduit
23
24 much easier. Moreover, because the 30° angle corresponds to a vertical handle of the tool,
25
26 the markings do not have to be checked but the correct bend is achieved when the handle is
27
28 vertical. There is also an issue of working with the bender when the work has to be
29
30 conducted in dangerous settings, such as three stories up on a scaffold, where the footing
31
32 consists of no more than ¾-inch plywood sheets.
33

34
35 Electricians also develop methods that do not use specific angles at all. We documented
36
37 one instance, where a journeyman explained to a fourth-year apprentice how to bend
38
39 electrical conduit tubing without using any angle measurement at all. The tubing is bent at
40
41 an arbitrary angle and then placed against a wall. The correct length is achieved by moving
42
43 a square alongside the wall until the distance to the wall-oriented side of the pipe surface
44
45 corresponds to the desired offset. The tubing is marked and the conduit tubing bent at the
46
47 mark until the pre- and post-offset pipes are parallel. In this manner, no calculations are
48
49 required at all because the process has been reduced to a simple measurement of distance.
50

51
52 Whereas in their college course, apprentices practice on relatively short pieces of metal,
53
54 in the field they have to work with the conduit tubing that will cover the entire lineal
55
56 distance. This is an important issue, as the termination of rigid tubing – involving cutting,
57
58 reaming, and threading – has to be accomplished prior to bending. Because of the offsets
59
60 introduced, the lineal distance and the length of the pipe required do not coincide. Whereas
61
62
63
64
65

1
2
3
4
5 tables exist that tell the electrician how much the conduit “shortens” for each offset and
6
7 offset angle, most electricians in our study adjusted the length by using a hacksaw or
8
9 adjusted to nearby fittings by inserting tubing less than the recommended amount into the
10
11 counterpart. Rules of bending thereby also included the bending of rules.
12
13
14

15 *3.4 Electrical apprentices between college and workplace*

16
17 At the college, many apprentices struggle with the tasks that require application of
18
19 trigonometry and precise calculations of the pertinent quantities. Many students attending
20
21 the program including our observer participant complained and called into question the
22
23 usefulness of the pre-apprenticeship program and apprenticeship training courses.
24
25 Students describe their experience as “putting in time” that moves them along their training
26
27 trajectory. This is not unlike what we observe in other programs – such as the mariners we
28
29 studied returning to upgrade their certificates (Emad & Roth, 2008). Here, too, both
30
31 students and instructors knew that the course contents were irrelevant to the worksite, but
32
33 both parties colluded so that students were properly prepared – in contrast with being
34
35 more proficient on the worksite – to succeed in formal examinations on the basis of which
36
37 they would receive their certificates. For the students, college is the place where
38
39 “mathematics and science are taught,” which contrasts with the workplace, “where the real
40
41 job gets done.” There are therefore inherent tendencies toward a schism, where the college
42
43 emphasizes learner subjectivities and theory and where the workplace emphasizes workers
44
45 and their practical competencies. It might be tempting to theorize the apprentices’ back-
46
47 and-forth movements between college and work by means of the boundary crossing
48
49 concept. However, my research generally suggests that the gap between theory and practice
50
51 becomes part of the professional lore.
52
53
54

55
56 Much as in the fish hatcheries and mariner training programs we studied (Emad & Roth,
57
58 2008; Lee & Roth, 2004), the difference between college and work has its own discourse
59
60 that allows the interaction participants to draw on the difference as a resource or topic.
61
62
63
64
65

1
2
3
4
5 There are frequent articulations of differences between college and workplace methods,
6
7 such as when journeymen and more senior apprentices point out, in the context of a specific
8
9 job, how something would be taught in college and how things have to be done “in the real
10
11 world” and “on the job.”
12

13 Some of the students, like the apprenticeship researcher, do learn the theoretical
14
15 discourse which enables them to tell more junior colleagues about the differences between
16
17 college and work discourse about how the job is to be done – for example, how to correctly
18
19 cut, ream, measure, and bend electrical conduit tubing. The gap between the formal and
20
21 work discourses appears to arise from an epistemology that “tends to endorse the valuation
22
23 of abstract knowledge over actual practice and, as a result, to separate learning from
24
25 working, and, more significantly, learners from workers” (Brown & Duguid, 1991, p. 41).
26
27 Our ethnographic work shows that the electrical apprentices are treated on the job as
28
29 workers rather than as learners, even though the differences in status are acted out in that
30
31 the apprentices were asked to do the undesirable and repetitive tasks.
32
33

34 An important site for the knotworking between college, code, and work practice was the
35
36 course on Canada’s electrical code; as part of the formal educational setting, it therefore
37
38 differs from the informal settings (e.g., bars) where field ecologists learn much of their
39
40 trade (Roth & Bowen, 2001). Electrician apprentices spend a week in groups working
41
42 through the code and completed worksheet assignments. They had discussions with the
43
44 instructor, who also debriefed them. In this course, stories from the field constituted an
45
46 important resource for making sense of the code, which, in turn, led to a discourse in which
47
48 the familiar material practices were *en-coded*, that is, retold in terms of the Canadian
49
50 electrical code. Our ethnography shows that students actively drew on their own work-
51
52 related experiences and on the stories of others to respond to the examination questions of
53
54 the course. The stories produced the knot where code and (stories of) praxis came together
55
56 while taking a formal college course. Because of the relation between the two aspects, first-
57
58 year apprentices acquire a form of knowledge that more closely resembles case law than
59
60
61
62
63
64
65

1
2
3
4
5 the law as written. The ability to retell practical decision making and practical work in
6
7 terms of the code is important, as it allows the practitioner to articulate the legality of what
8
9 they have done. It is also an important aspect of thinking about the integration of two
10
11 lifeworld – college and work – rather than their differentiation into very different worlds
12
13 that require border crossing to get from one into the other. That is, apprentice and licensed
14
15 electricians point out the contradictions between the formal knowledge taught in college
16
17 and their everyday practices and these contradictions are integral part of the stories they
18
19 tell. But the contradiction is apparent in their work, because the electricians do their jobs in
20
21 such a manner that these meet the demands of the code – though it would be a stretch to
22
23 argue that the code drives or shapes the practice.
24
25

26 As apprentices participate in worksites, they become increasingly competent
27
28 practitioners, recognized by their peers for the contributions that they make to the job at
29
30 hand. Increasing subjectification – i.e., becoming a subject of activity – also means building
31
32 up a stock of stories that practitioners share with others in appropriate instances. In fact,
33
34 the stories not only encode practical knowledge but also the very process of
35
36 subjectification, as can be seen in the following field note, in which the apprentice talks
37
38 about a new workplace:
39
40

41 After months of being a disposable set of hands on the big industrial site, working
42
43 with Steve just about brings on culture shock. I've shed my fifteen-pound tool belt,
44
45 and walk around with a "data geek" pouch with precision cutters and termination
46
47 tools. I've been introduced to, and routinely discuss my work with, the network
48
49 manager, a system analyst, and a couple of programmers. I'm a player in a team, not
50
51 just of electricians, but of network builders. I wear a dress shirt to work, and my
52
53 jeans stay clean. Some of the guys at the other site say that data is for sissies, but I
54
55 happen to like it (maybe they're just envious).
56
57

58 In this new worksite, the very comportment and dress is constitutive of the subject, and
59
60 appearing differently than others would be an affront to the team as a whole. A 15-pound
61
62

1
2
3
4
5 tool belt is the appropriate attire in one situation, whereas precision cutters are
6
7 characteristic of the other. Attire and tools are constitutive of who the apprentice becomes,
8
9 and, therefore, of the process of subjectification characteristic of the particular activity
10
11 system.
12
13
14

15 **4 Subjectification, personality, and the demise of boundaries**

16
17 This study was designed to investigate (a) the geometrical practices of electrician
18
19 apprentices in college and on the job and (b) how the relation between differing practices
20
21 come to be handled. From the cultural-historical activity theoretic perspective underlying
22
23 this study, college and workplace belong to different forms of activity. Because activity is
24
25 the minimal unit that makes sense (Leontjew, 1982), participating in a different activity
26
27 means that the person is differently constituted as subject in each activity system. This
28
29 process of subject development is denoted by the term *subjectification*. Boundary crossing
30
31 theories (see review in Akkerman & Bakker, 2011) tend to theorize the differences that
32
33 arise from being a different subject and engaging in different practices in terms of
34
35 boundaries that the person has to cross. The present study shows, however, that the
36
37 apprentices integrate these differences between school and workplace not only by living
38
39 through them in person but also by accounting for these differences in their workplace
40
41 stories and narratives about work. Moreover, this study shows that “workplace” is not a
42
43 unitary experience but that an apprentice may be subject to “culture shock” when s/he
44
45 moves from one type of electrical work to another. Thus, the foregoing data show that
46
47 Racca was constituted as a very different subject while working on construction and while
48
49 building computing networks. From a cultural-historical activity theoretic perspective, each
50
51 form of subjectivity that the subject-related differences imply is but a knot in a much more
52
53 complex knotwork that in its entirety constitutes the personality.
54
55
56

57
58 In the course of their apprenticeship arrangement, electricians spend 3 months at
59
60 college and 9 months at work during each of the 4 years of the training. Therefore, the
61
62
63
64
65

1
2
3
4
5 apprentices in this program experience 7 times the transition from college to work and vice
6
7 versa. The transitions, as much as the subjectivities that are aspects of each particular
8
9 activity, are therefore integral to becoming and being a certified electrician journeyman
10
11 and, thus, constitutive of the person, that is, constitutive of his/her personality. In the
12
13 process, the individual electrician also comes to embody the contradictions between the
14
15 different activity systems, contradictions that are aspects of the stories that contribute to
16
17 making a licensed journeyman electrician who s/he is. But they come to embody these
18
19 contradictions in different ways, because the knots related to workplace and college activity
20
21 appear in different locations in their individual knotworks and, therefore, not only
22
23 constitute different personalities but also constitute these differently. Thus, for Racca the
24
25 journeyman certification was but one of the possibilities of earning a living and he never
26
27 worked full-time in the profession following his licensure; other participants in our study
28
29 were at the beginning of their career, and becoming a journeyman electrician was the first
30
31 thing they did following high school; and yet others had worked on the job, going through
32
33 the apprenticeship training only to become certified to legally do what they have already
34
35 done. There is therefore both an experienced contradiction between college and workplace
36
37 forms of knowledge and subjectivities and a differential integration of these contradictions
38
39 into the total knotwork that constitutes the personality of each apprentice. Having a stock
40
41 of stories to talk about the contradictions is as much part of being a recognized practitioner
42
43 as is competent practice, the narratives that encode the do's and don't's of the workplace,
44
45 the translations between practice and formal code, and the justifications that a job done is
46
47 in fact consistent with and implements the code.
48
49
50

51 This study among electricians and electrician apprentices exhibits the radical
52
53 differences between the (mathematical) practices of bending electrical metal tubing in
54
55 college and in the workplace. As could be expected from cultural-historical activity theory,
56
57 the forms of consciousness that they exhibit to each other also are radically different, in
58
59 part related to the different tools that are available or that must be used (trigonometry in
60
61
62
63
64
65

college, bender in workplace praxis). This raises questions as to the usefulness of vocational courses that emphasize formal mathematics that is treated as irrelevant in the workplace. Similar contradictions arise when new tools are introduced to the work; these contradictions give rise to old-timer stories about what they do with the old tools where users of new tools “screw up.” In this case, we might be tempted to use *boundary crossing* as the pertinent analytic category. However, I suggest that this is neither necessary nor useful. Instead we may draw on *personality* as the relevant analytic category. It orients us to the knotwork of object/motives that holds together the different activities in which a person participates, together with the category of *subjectification*. This pair of analytic categories describes and theorizes the experience of the *persons* much better than boundary crossing as they articulate the differences all the while integrating them into a higher order (dialectical) unit. It better aligns with a science of the subject, where the viewpoints of persons on learning take precedence over the theoreticians’ perspectives that are characteristic of the social sciences (e.g., Holzkamp, 1993). After all, even though the electrical apprentices felt formal mathematics as unhelpful and useless, they repeatedly moved back and forth between the different activities with a sense of coherence: “Because our true body is a subjective body it is the *unity of all the powers*, of all the senses that make it up” (Henry, 2005, p. 192, emphasis added).

Going to college as part of the apprenticeship program, however despised, is an integral part of becoming a licensed electrician. At work, nobody uses the trigonometry that they have to learn to pass the test and get their license. But it is part of the process of subjectification within schooling, a process that most participants feel subject and subjected to. In the workplace, however, especially the more advanced electrician apprentices experience greater levels of agency, even though during their first year they are often subjected to workplace-specific demands, such as doing the least-liked and appreciated aspects of the total project. Most importantly, having gone to college allows the journeyman electricians to work according to the electrical code *all the while* meeting practical

1
2
3
4
5 workplace constraints. In fact, they have to know that their job meets legal standards, as all
6
7 electrical work is subject to formal inspection by a member of the *Electrical Inspectors'*
8
9 *Association of British Columbia*, which had been created to achieve uniform interpretation of
10
11 the code.
12

13
14 There are not just differences between college and workplace: the electricians'
15
16 discourse about those differences is both topic and resource in the conversations that
17
18 constitute their community of practice. The integration and differentiation of the two forms
19
20 of practices is an integral aspect of being a practicing electrician (as it is an integral part of
21
22 the mariners, fish culturists, or ecologists we studied). Electricians often make reference to
23
24 what is taught and what is done much in the same way that they refer to the *Code* when
25
26 talking about what is "the law" and what is being done. Leontjew's category *personality*
27
28 appears appropriate because it focuses on the *integration* of the *different* object/motives
29
30 (activities) and their hierarchical ordering of knots rather than merely on the boundaries
31
32 between them. The location of the college and workplace knots in the individual
33
34 electrician's hierarchy may change in and through participation in an activity – which
35
36 allows us to understand that some practitioners eventually move from practice to become
37
38 teachers in college programs. The embedded researcher in this study (Racca) used his MA
39
40 study as a resource to become part of a government panel on learning assessment and the
41
42 trades while in his third year of his four-year program. That is, the electrician apprentices
43
44 undergo two processes of subjectification by participating in the college and workplace,
45
46 being both subjects of and subject(ed) to the activities. They *integrate* these as part of the
47
48 electrician personality they develop, which in fact constitutes a knotwork that holds the
49
50 respective experiences together in the same person, but attributing different places to these
51
52 in the resulting hierarchy.
53
54

55
56 There is transfer (i.e., "knot-working") of practices to the extent that the stories they tell
57
58 when making sense of problematic issues are carried from one activity (e.g., schooling) to
59
60 the other (e.g., doing electrical work). In workplace stories, there are references to the
61
62
63
64
65

1 college, and in college, workplace stories are used to make sense of the college course on
2
3
4
5 code. However, the different forms of mathematics are tied to and contingently used within
6
7
8 each activity with little reference to the corresponding practice in the other activity. Even
9
10
11 practitioners who become teachers at the college can do little to overcome the distinct
12
13
14 practices. Instead, our research shows that they collude with the students, preparing them
15
16
17 to successfully pass the examinations all the while knowing that much of what the students
18
19
20 learn will be irrelevant to their workplace practice. These distinctions are not only part of
21
22
23 the lore of the field but also integral to the personalities (identities) of practicing
24
25
26 electricians that the apprentices become through the training process described here. Thus,
27
28
29 on the day before I worked on the revisions to this article, a plumber who had immigrated
30
31
32 from Finland in 1971, told me about how he passed the multiple choice examination for his
33
34
35 license “even without understanding much English” and by “learning the patterns of
36
37
38 question and correct responses.” Such stories are integral part of a practice and the
39
40
41 personalities of the practitioners that constitute the community. As a result of my
42
43
44 ethnographic work of very different professions and practices, I conclude that the
45
46
47 differences between college and workplace are better explained by the concept of
48
49
50 personality, which emphasizes integration, continuity, together with difference, rather than
51
52
53 by the concept of boundary crossing, which emphasizes difference and conflict.
54

59
60
61
62
63
64
65

5 Coda

Using a case study from the apprenticeship programs and training of electricians, I
outline a cultural-historical activity theoretic approach to the question of the discontinuities
of social practices. I propose *subjectification* and *personality* as a set of analytic categories to
capture the continuity of experiences that an individual person feels even if s/he moves
across activities implying different subjectivities and, therefore, engages in different
cultural practices where s/he is constituted differently as the subject of activity.

Figure 1. Electrical metal conduit into the main breaker panel and between breaker panels protects and grounds the wires; the “Certificate of Inspection” on the right guarantees that the house has been wired according to the Electrical Code of Canada. Electricians endeavor to have as few of the visible joining pieces as possible.

Figure 2. The magic circle is a device that is to assist students in remembering how to calculate trigonometric functions.

Figure 3. In college, electrician apprentices are asked to use trigonometry to decide where bends in a parallel offset have to be placed, how far from the object, and what the distance between the bends are given the bending angle.

Figure 4. This front and back view of a bender shows that much of the information required in praxis is engraved on the tool.
