The boron-mediated ketone-ketone aldol reaction

Katie M. Cergol, Peter Turner† and Mark J. Coster*

School of Chemistry, University of Sydney, NSW 2006, Australia

Abstract—The first examples of the directed, boron-mediated aldol reaction between different ketones are presented. Transformation of a variety of ketones to their corresponding boron enolates with Chx₂BCl/Et₃N, followed by reaction with acceptor ketones in diethyl ether, and oxidation of the resultant boron aldolate (H₂O₂, MeOH/pH 7 buffer), provided the aldol addition products. The reaction was most facile when cyclic ketones were used, with the highest yields obtained for the reaction of boron enolates with cyclohexanone as the acceptor.

Keywords: boron aldol, ketones, sterically congested.

The directed aldol reaction is one of the most valuable carbon-carbon bond-forming processes available to the organic chemist.⁰ Amid the plethora of available procedures, the aldol reaction of boron enolates with aldehydes has found particularly widespread application in stereoselective organic synthesis.² Attractive features of this process include the highly predictable regio- and stereoselective outcomes that can be achieved with a variety of ketones and aldehydes, under mild conditions. The many applications of this reaction to the late-stage coupling of complex molecules in the area of natural product synthesis,³ serve to highlight the reliability and functional group tolerance of this transformation. However, despite the exemplary nature of the boron-mediated aldol reaction of ketone-derived enolates with acceptor aldehydes, there have been no reports of the reaction of boron enolates with acceptor ketones to give aldol addition products in synthetically useful yields. In contrast to the myriad of procedures available for directed aldol reactions employing aldehydes as acceptors, there are relatively few general procedures for the directed aldol reaction of two different ketones. Reactions of ketone-derived, Sn(II),⁴ Ce(III),⁵ and Ti(IV)⁶ enolates with acceptor ketones have been reported, however, examples of the direct cross-coupling of differing aliphatic ketones have been limited to the last of these procedures.⁶a,c

As part of a program directed toward the synthesis of sterically-congested 1,3-diols, we have investigated the boron-mediated aldol reaction between two different ketones for the construction of highly substituted β-hydroxy ketones. We now report the reaction of dicyclohexylboron enolates, derived from an assortment of aliphatic ketones, with a variety of acceptor ketones, to provide the aldol addition products under mild conditions.

Initial experiments involved the enolisation of cyclohexanone (Chx₂BCl, Et₃N, Et₂O),⁷ to give the corresponding boron enolate in situ, and subsequent reaction with acetone or 3-pentanone (Et₂O, 5 °C, 16 h), followed by treatment with H₂O₂ in MeOH/pH 7 buffer (Scheme 1). The reaction with acetone afforded the expected aldol product 1a in low yield (15%), along with a comparable quantity of compound 2 (12%), presumably resulting from the reaction of cyclohexanone with its corresponding dicyclohexylboron enolate. In contrast, attempts to extend this reaction to 3-pentanone failed to give any of the desired aldol product 1b, providing 2 (11%) as the sole isolated product. Changing the reaction solvent to pentane led to only trace quantities of aldol products.

While the low yields obtained using the simple acyclic ketones, acetone and 3-pentanone, suggested that ketones are relatively unreactive towards boron enolates, as implied by the lack of literature precedence in this regard, we were intrigued by the apparent reactivity of cyclohexanone as an acceptor under these conditions.
The boron-mediated aldol reaction of simple cycloalkanones was systematically studied for five- to seven-membered rings (Table 1). In all cases studied, the desired cross aldol product could be isolated in low to good yields. The highest yields were obtained when cyclohexanone was used as the acceptor ketone (entries 1 and 6, 70% and 64% respectively). The lower yields obtained with cyclopentanone or cycloheptanone as the acceptor under the standard reaction conditions, are attributed to a slower rate of reaction. In the case of the cycloheptanone-derived enolate reacting with cyclopentanone (entry 5), increasing the reaction time from 16 h to 40 h led to a moderate increase in yield (41 → 61%). Furthermore, reactions involving cyclohexanone as the donor ketone (entries 3-4) resulted in the formation of small amounts of 2 (5-8%). In contrast, when cyclopentanone or cycloheptanone were used as the donor ketone, none of the analogous “self-aldol” product was obtained (entries 1-2, 5-6). These findings serve to demonstrate the high reactivity of cyclohexanone as an acceptor ketone in these reactions.

Variation of the reaction conditions, e.g. rate/order of addition, enolisation temperature (−78 °C) and solvent (pentane, CH₂Cl₂), failed to improve the overall yield of aldol product or decrease the quantity of 2 produced in these reactions. Furthermore, the use of the corresponding di-n-butylboron enolates, gave lower yields of the desired aldol products (<20%). In these cases, the reactions were conducted in CH₂Cl₂, which we have found to be a greatly inferior solvent for this aldol addition, and therefore the low yields likely illustrate the effect of solvent on the rate of the reaction, rather than the nature of the boron ligands.

The yields obtained using cyclic ketones as acceptors in these aldol reactions correspond with their rates of reduction with sodium borohydride, reflecting the relative reactivity of each of these ketones toward nucleophilic addition. Molecular mechanics calculations have been used to rationalise the differing reactivity of cyclic ketones according to ring size. Of the acceptor cycloalkanones...
studied here, only cyclohexanone has been calculated to be more strained than the corresponding hydrocarbon, cyclohexane. Moreover, the inability to have an alkyl group eclipsing the carbonyl has been used to rationalise the increased strain of cyclohexanone relative to 3-pentanone. Hence, cyclohexanone represents a particularly reactive acceptor ketone for the boron-mediated aldol reaction, due to lack of steric hindrance about the carbonyl group and release of ring strain upon nucleophilic addition.13 Noting the superior results obtained with cyclohexanone as the acceptor in these boron-mediated ketone-ketone aldol reactions, the scope of this transformation was further explored using a variety of ketone donors and cyclohexanone as the acceptor (Table 2).

a Isolated yields.
'bAldol reaction at 5 °C for 40 h.

The aldol reaction of acyclic donor ketones, acetone and 3-pentanone, with cyclohexanone proceeded less rapidly, requiring 40 h to yield the corresponding aldol products, 4b and 4c, respectively (entries 2 and 3).14 The aldol reaction with a heterocyclic donor ketone, N-benzyl-4-piperidone, provided 4d (entry 4) in good yield (75%).

The aldol products produced by the methods outlined here could, in principle, be reduced to 1,3-diols by a variety of methods. In order to verify the stereochemical assignments of cis- and trans-4a (Table 2, entry 1), the major diastereomer was subjected to NaBH(OAc)₃ in dichloromethane (Scheme 2).15 The corresponding, crystalline 1,3-diol 5 was produced as the major diastereomer (96:4 dr by GC and ¹H NMR analysis).

The aldol reaction proceeded smoothly with 2-methylcyclohexanone as the donor ketone (entry 1), via regioselective enolate formation, providing the aldol product 4a in good yield (75%), as a 2:1 mixture of cis and trans diastereomers, respectively. The stereochemistry of each of these was assigned on the basis of ¹H NMR coupling constants and NOESY spectra, and confirmed by X-ray crystallographic analysis of a derivative, vide infra.

The structure and relative stereochemistry of 5 were determined by single crystal X-ray diffraction,16-21 which confirmed the aldol reaction gave predominantly the cis-diastereomer, while reduction occurred via equatorial delivery of hydride to cis-4a (Figure 1). This is in contrast to the reduction of syn- and anti-cyclohexanone–benzaldehyde aldol adducts with NaBH(OAc)₃, which provide as the major products, 1,3-diols resulting from axial delivery of hydride.15

Inspection of models, in relation to Evans’ mechanistic studies on triacetoxyborohydride mediated reduction of hydroxyketones,22 suggests that the stereoselectivity observed in the reduction of cis-4a to 5 may arise by internal delivery of hydride via a boat-like transition state TS-1, leading to the axial alcohol.23 The boat-like transition state, TS-2, for internal delivery of hydride in an axial sense suffers from severe 1,4-steric interactions between the acetoxy group on boron and a CH₂ of the cyclohexanone ring. Examination of alternative, chair-like transition states for internal delivery of hydride to either face of the ketone, suggests these are unfavourable in each case due to 1,3-diaxial interactions between an acetoxy group and an axially-oriented CH₂ of one of the six-membered rings.24
In summary, the boron-mediated ketone-ketone aldol reaction has been shown to be a facile process with cyclic acceptor ketones. In particular, cyclohexanone was found to react with a variety of boron enolates to afford the cross aldol products in good yields. Further efforts to explore the stereoselectivity of this reaction with substituted ketones, and to functionalize the aldol products toward sterically-encumbered 1,3-diols and related compounds, will be reported in due course.

9. Representative procedure: A solution of Chx2BCl (241 μL, 234 mg, 1.1 mmol, 1.1 equiv.) in EtO (4 mL) at 0 °C was treated with Et3N (167 μL, 121 mg, 1.2 mmol, 1.2 equiv.) dropwise, followed by cyclopentanone (88 μL, 84 mg, 1.0 mmol) and the resulting mixture was stirred for 45 minutes. Cyclohexanone (114 μL, 108 mg, 1.1 mmol, 1.1 equiv.) was added and the mixture was left at 5 °C for 16 h. A pre-mixed solution of 6:1 MeOH (6 mL) and pH 7 buffer (1 mL) was added at 0 °C, followed by a pre-mixed solution of 2:1 MeOH (2 mL) and 30% H2O2 (1 mL), and the mixture was warmed to rt. After 2 hours at rt the mixture was diluted with Et2O (10 mL) and H2O (10 mL), the layers were separated and the aqueous phase was extracted with Et2O (3 × 10 mL). The combined organic extracts were washed with sat. NaHCO3 (15 mL), and brine (15 mL), dried (Na2SO4), and concentrated in vacuo. Purification by flash chromatography (SiO2, 25:75 EtOAc/hexanes) provided 3a (128 mg, 70%) as a colourless oil: IR (NaCl, thin film) 3493, 2934, 2858, 1724, 1448, 1402, 1356, 1271, 1250, 1155, 1065, 1034, 1001 cm⁻¹; 1H NMR (400 MHz, CDCl3) δ 3.43 (1H, s), 2.32-2.24 (1H, m), 2.19-1.90 (4H, m), 1.72-1.52 (6H, m), 1.44-1.30 (5H, m), 1.12-1.02 (1H, m); 13C NMR (100.6 MHz, CDCl3) δ 222.9, 72.6, 58.3, 39.7, 36.2, 32.6, 25.8, 25.5, 21.2, 21.1, 20.1; HRMS (+ESI) Calc. for C11H18O2Na [M + Na]+: 205.1199, found: 205.1200. In cases where a low to moderate yield of the aldol product was obtained, t.l.c analysis suggested that some unreacted starting materials remained. However, these starting materials were too volatile to recover from the reaction mixtures. Conducting the reaction at temperatures above 5 °C led to lower yields and the production of undesired side products.
13. No aldol reaction is observed when 2-methylcyclohexanone is used as the acceptor ketone, demonstrating the strong influence of a 2-alkyl substituent on the reactivity of the acceptor. This may be attributed to increased steric hindrance about the carbonyl group, and a diminished contribution from strain relief.
14. The yield of 4e was also limited by difficulties in isolation, due to the significant volatility of this compound.
16. Structure Determination for 5: The crystals fragmented on cutting, accordingly a larger than ideal crystal was used for the data collection. A Bruker SMART 1000 CCD diffractometer with graphite monochromated MoKα radiation from a sealed tube was used to collect data at 150(2) °K, using o scans. Data integration and reduction were undertaken with SAINT and XPREP,[17] and subsequent computations were carried out with the WinGX[18] and XTAL[19] graphical user interfaces. The structure was solved in the space group P21/n (14) by direct methods with SIR97,[20] and extended and refined with SHELXL-97.[21] The non-hydrogen atoms were modelled with anisotropic displacement parameters, and the hydrogen atom sites were located and
modelled with isotropic displacement parameters. *Crystal Data:* Formula C$_{13}$H$_{24}$O$_{2}$, $M$ 212.32, space group $P2_1/n$ (No. 14), $a$ 11.783(2), $b$ 6.3284(11), $c$ 15.914(3) Å, $\beta$ 97.095(3), $V$ 1177.6(3) Å$^3$, $Z$ 4, crystal size 0.628 by 0.088 by 0.049 mm, colour colourless, habit acicular, temperature 150(2) Kelvin, $\lambda$(MoK$_{\alpha}$) 0.71073 Å, $\mu$(MoK$_{\alpha}$) 0.078 mm$^{-1}$, 2$\theta$ max 56.62, $hk\ell$ range -14 14, -8 20, $N$ 1150, $N_{\text{obs}}$ 2812 ($R_{\text{merge}}$ 0.0616), $N_{\text{obs}}$ 1650 ($I > 2\sigma(I)$), $N_{\text{var}}$ 232, $R_1(F) 0.0397$, $wR_2(F^2) 0.0921$, GoF(all) 1.085, $\Delta\rho_{\text{min,max}}$ -0.196, 0.286 e Å$^{-3}$. Crystallographic data (excluding structure factors) for 5 has been deposited with the Cambridge Crystallographic Data Centre as supplementary publication number CCDC 254676. Copies of the data can be obtained free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: +44(0)-1223-336033 or email: deposit@ccdc.cam.ac.uk].

23. Although it is surprising that this reaction occurs in the absence of acetic acid as co-solvent, the one equivalent of acetic acid released on exchange of the acetoxy for the substrate alkoxy group, at boron, may be sufficient to facilitate the reaction, given the facile nature of cyclohexanone reduction (Ref. 11).
24. An alternative mechanism involving intermolecular hydride delivery cannot be ruled out.
