Abstract
In dye-sensitized solar cell (DSSC) photoanodes, tin dioxide (SnO₂) structures are promising alternative semiconducting oxide to the conventional titania (TiO₂), but they suffer from poor photovoltaic (PV) efficiency caused by insufficient dye adsorption and low energy value of the conduction band. A hybrid structure consisting of SnO₂ and reduced graphene oxide (SnO₂–RGO) was synthesized via a microwave-assisted method and has been employed as a photoanode in DSSCs. Incorporation of RGO into the SnO₂ photoanode enhanced the power conversion efficiency of DSSC device by 91.5%, as compared to the device assembled without RGO. This efficiency improvement can be attributed to increased dye loading, enhanced electron transfer and addition of suitable energy levels in the photoanode. Finally, the use of RGO addresses the major shortcoming of SnO₂ when employed as a DSSC photoanode, namely poor dye adsorption and slow electron transfer rate.

Keywords
Photovoltaic, dye-sensitized solar cells, photoanodes, tin dioxide, graphene
1. Introduction

One of the mature developments in new energy production approaches is the dye-sensitized solar cell (DSSC) [1]. For a broad perspective of the field, there are several good reviews available [2-4]. A typical DSSC photoanode is made using a transparent conducting oxide (TCO) substrate, wide band gap oxide semiconductor and dye sensitizer. A nanocrystalline TiO$_2$ semiconductor is mostly used as the semiconductor due to its unique properties [5]. Despite the high power conversion efficiencies (PCEs) achieved by devices fabricated with TiO$_2$ photoanodes [6-8], the intrinsic low carrier mobility of TiO$_2$ is a matter of great concern [9, 10]. This issue has led many researchers to probe the development of alternative photoanode materials.

Among many alternative semiconductors, SnO$_2$ has been the subject of numerous investigations [11-13]. This is partially due to the fact that SnO$_2$ has a higher electron mobility than TiO$_2$ [14, 15]. Since the first use of SnO$_2$ in DSSCs, significant developments have been made in the SnO$_2$ photoanodes [11, 13]. These developments include morphology control, doping with various species, surface modification, and hybrid structures with other oxide semiconductors [16-18]. Despite the considerable effort to improve SnO$_2$ based photoanodes, a major challenge for SnO$_2$ based DSSCs is still their low performance caused by poor dye adsorption capability [19]. Additionally, the SnO$_2$ photoanode based DSSCs suffer from a low open circuit voltage ($V_{oc}$) value due to the intrinsically low energy of the conduction band of SnO$_2$ [20]. Therefore, addressing these issues is of great importance for the development of SnO$_2$ based photovoltaic (PV) cells. Moreover, although SnO$_2$ possesses higher electron mobility than TiO$_2$, further improvement in the electron transport in SnO$_2$ photoanode would be of great value to maximize the efficiency.

Due to their excellent conductivity, carbon nanotubes (CNTs) and graphene can act to improve electron transport and reduce the charge recombination which results from sluggish charge transport of semiconducting oxide based photoanodes; thus significantly enhancing the PCE of PV cells [21-26]. Over the past few years, researchers have incorporated graphene derivatives into various TiO$_2$ structures and shown remarkable efficiency enhancement [27-30]. However, until now, there has been no report on the use of graphene structures in SnO$_2$ photoanodes for DSSCs. Moreover, the kinetics of dye adsorption and performance enhancement for carbonaceous photoanodes is still unclear, with some studies suggesting contrary results [21, 28, 29, 31, 32]. Therefore, exploring the effect of graphene or reduced graphene oxide (RGO) in SnO$_2$ photoanode based DSSCs would be valuable.
Herein we report a facile preparation of hybrid structures based on morphologically controllable SnO$_2$ combined with RGO for use as a photoanode in DSSCs. To the best of our knowledge, this work is the first effort involving the application of a graphene structure in SnO$_2$ photoanode based DSSCs. We found that the incorporation of RGO into the SnO$_2$ film not only enhances the electron transfer rate of the photoanode, it also increases the adsorption of dye molecules into the film, thus greatly improving DSSC performance.

2. Experimental
2.1. Materials
All chemicals were purchased from Sigma-Aldrich and used without further purification, unless otherwise stated. Tin (II) chloride dihydrate (SnCl$_2$·2H$_2$O) powder (>99% purity, Merck) was used as a starting material. Flourine-doped tin oxide (FTO) coated glass electrode with a sheet resistance ($R_s$) of ~12 $\Omega$/$\square$ (TCO30-8), Ruthenizer 535-bisTBA (N719 dye), iodide/tri-iodide electrolyte (Iodolyte Z-50), DuPont Surlyn® (Meltonix 1170-60) and Platinum catalyst (Platisol T) were obtained from Solaronix, Switzerland.

2.2. Preparation of graphene oxide
Graphite oxide was prepared from natural graphite using the approach from Marcano et al. [33]. Briefly, a 9:1 (v:v) mixture of sulfuric acid (95-98% H$_2$SO$_4$) and phosphoric acid (85% H$_3$PO$_4$) (240:27 mL) was kept in the cold room (3-5°C) until it was added to a mixture of graphite flakes (2 g) and potassium permanganate (99% KMnO$_4$) (12 g). The oxidation process of graphite was carried out by stirring the mixture at ~50°C for 12 h. Upon completion, the reaction was cooled down to room temperature and poured onto ice (approximately 300 mL) with 30% hydrogen peroxide (H$_2$O$_2$) (2 mL). The mixture was then washed with distilled (DI) water, 30% hydrochloric acid (HCl) and ethanol (x 2 times). For each sequential wash, the product was centrifuged at 4400 rpm for 3 h and the supernatant decanted away. The obtained light brown sample was then vacuum-dried overnight at room temperature. Then the as-prepared graphite oxide was exfoliated in water (1 mg mL$^{-1}$) by bath ultrasonication (Elma, Germany) for 60 min to obtain homogenous graphene oxide (GO) dispersion.

2.3. Synthesis of SnO$_2$-RGO hybrid
The SnO$_2$-RGO hybrid was prepared using a facile microwave-assisted method [34]. In a typical process, six glass beakers containing 90 mL DI water and different GO content (0 mg,
2 mg, 4.5 mg, 7 mg, 12 mg and 50 mg) were ultrasonicated for 2h. Meanwhile, 1.5 g of SnCl₂·2H₂O powder was added into 200 mL of 0.02M HCl solution. Then the previously prepared GO dispersions were added into the SnCl₂·2H₂O solutions, followed by stirring for 30 min. The as-obtained mixtures were then reacted using a microwave technique (StartSYNTH Microwave Synthesis Labstation, Milestone s.r.l) for 5 min under 600 W power. The temperature was adjusted to 90°C during the microwave treatment. After cooling to room temperature, the obtained precipitates were centrifuged at 2000 rpm for 10 min and washed several times with DI water, followed by drying overnight at 80°C in an oven to obtain SnO₂-RGO powders. Finally, six samples of different RGO content (0 wt%, 0.2 wt%, 0.45 wt%, 0.7 wt%, 1.2 wt% and 4.75 wt% in the hybrid) were prepared and have been used for DSSC fabrication. It should be noted that the amount of SnO₂ in these samples was not changed. For the calculation of the RGO concentration in the hybrid, it was assumed that the conversion of SnCl₂·2H₂O to SnO₂ is 100% based on the lack of Cl peak observed in various hybrid characterizations.

2.4 Device fabrication

Firstly, viscous SnO₂ and SnO₂-RGO pastes were prepared from the previously prepared six samples according to the established procedures described in the literature [35]. FTO coated glass substrates were cleaned by a detergent (Pyroneg), followed by washing with Milli-Q water, acetone and ethanol under ultrasonication for 10 min each and subsequently dried with a nitrogen gas. The cleaned FTO glass substrates were immersed in a 40 mM TiCl₄ aqueous solution at 70°C for 30 min. Then the TiCl₄ treated FTO electrodes were coated with the SnO₂ and SnO₂-RGO pastes by a doctor blade technique to prepare the photoanodes. All photoanode films were obtained by applying two layers of adhesive scotch tape (Magic™ Tape, 3M) on the FTO electrode, which gives a film thickness of ~15 µm [36]. It is well established that the photoanode thickness of 12-16 µm is the optimum condition for achieving high DSSC performance [36-38]. After the deposition of SnO₂ and SnO₂-RGO pastes onto the FTO substrates, the photoanode films were gradually heated under an air flow at 125°C for 5 min, 325°C for 5 min, at 375°C for 15 min and at 450°C for 30 min, followed by cooling to room temperature. Then the films were again soaked in 40 mM TiCl₄ solution at 70°C for 30 min, followed by sintering at 450°C for 30 min. After cooling to ~50°C, the prepared films were immersed into 0.5 mM N719 dye in an ethanol solution for 20 h at 40°C. Then, the dye adsorbed photoanodes were washed with ethanol to remove non-adsorbed dye from the films.
In the meantime, platinum (Pt) catalyst was coated onto FTO substrates from Pt precursor (Solaronix) by a brush-painting method to prepare the counter electrodes. The dye-adsorbed photoanodes and Pt counter electrodes were assembled into a sealed sandwich-type cell, with a 60 µm thick hot-melt sealing Surlyn between each layer. The electrolyte solution, Iodolyte Z-50 (Solaronix), was introduced into the cell via a vacuum-filling method through an injection hole on the counter electrode side. Finally, the hole was sealed with scotch tape.

2.5. Characterization

Scanning electron microscopy (SEM) images were obtained using an Inspect F50 SEM (FEI) with accelerating voltage of 10 kV. Energy dispersive X-ray spectroscopy (EDX) analysis was completed on the same system with Team EDS Octane Pro (EDAX) attachment. Elemental compositions of the samples were analyzed at binding energy ranging from 0 eV to 1200 eV using a X-ray photoelectron spectroscopy (XPS), Leybold Heraeus LHS-10 with a SPECS XR-50 dual anode source operating at 250W. The Mg-Kα source, which has energy of 1253.6 eV, was used for the XPS analysis. X-ray diffraction (XRD) patterns were carried out on a powder X-ray diffractometer at 40 kV and 15 mA in the range of $2\theta = 3–80^\circ$ using Cu Kα radiation (Model Miniflex 600, Rigaku, Japan). Attenuated Total Reflection-Fourier Transform Infrared Spectroscopy (ATR-FTIR) spectra were acquired over a wavenumber range of 4000-500 cm$^{-1}$ in transmission mode using a Frontier FTIR spectrometer (Perkin Elmer, USA) with a germanium crystal. Raman spectroscopy was carried out on LabRAM HR Evolution spectrometer (Horiba Jobin Yvon, Japan). Raman spectra were collected using a 532 nm laser (mpc 3000) as the excitation source. A 50x objective was used with a confocal hole size of 100 µm. Auger spectromicroscopy “PHI 710 scanning auger nanoprobe” operating at base vacuum below 1x10$^{-9}$ Torr was used to analyse the elemental analysis of the samples. Sputtering samples for the analysis was performed using ultra high purity Argon. Data was collected using an electron beam of 10 kV, 10nA.

To determine the adsorbed amount of dye molecules in the SnO$_2$ and SnO$_2$-RGO films, the dye in the films was dissolved in 0.1 M NaOH aqueous solution and then measured by a Varian Cary 50G UV-vis Spectrophotometer at wavelengths ranging from 300 to 1000 nm. Sheet resistivities were performed on the microscope slide substrate coated with SnO$_2$-only and/or SnO$_2$-RGO hybrid using a four point probe technique (KeithLink Technology Co., Ltd. Taiwan). The photocurrent–voltage ($J-V$) characteristics were investigated using a Keithley 2400 SMU instrument and recorded using a custom LabView Virtual Instrument program. A standard silicon test cell with NIST-traceable certification was used to calibrate
the power density as 100 mW cm\(^{-2}\) at the sample plane of the collimated xenon-arc light source, which was passed through an AM 1.5G filter. The active area of each device was 0.25 cm\(^2\). The \(J-V\) curves were measured in the air through reverse-scan direction from 1 V to -1 V. Incident-photon-to-current conversion efficiency (IPCE) measurements as a function of wavelength ranging from 400 nm to 800 nm were taken by passing chopped light from a Xenon source through a monochromator and onto the devices.

3. Results and discussion

The preparation of SnO\(_2\)-RGO hybrid is shown in Scheme 1. Firstly, SnCl\(_2\)-2H\(_2\)O powder (Fig. S1) was mixed with GO (Fig. 1a) in aqueous hydrochloric acid (HCl, 0.02 M) to form a homogenous solution, which was stirred and reacted using a microwave technique. During this process, GO was reduced and is termed “RGO”. Then, the resulting product was centrifuged and dried to obtain a SnO\(_2\)-RGO hybrid. For comparison, the same process was carried out in the absence of GO to produce only SnO\(_2\) [36].

The SEM image in Fig. 1b shows that the synthesized SnO\(_2\) is a 1 dimensional (1D) microstructure with a rod-like shape. It is worth noting that 1D structures can provide fast electron transport pathway [39]. Fig. 1c depicts the SEM image of the SnO\(_2\)-RGO hybrid, which demonstrates clear differences compared to GO (Fig. 1a) and SnO\(_2\)-only. It can be seen that the SnO\(_2\) micro-rods were well mixed and wrapped in the RGO flakes, as expected, to form the hybrid material. As shown in Fig. 1d and 1e, during the microwave-assisted synthesis, small SnO\(_2\) nanoparticles were also formed on both SnO\(_2\) rods and RGO flakes which are expected to be beneficial for dye adsorption.

Fig. 2a shows the XRD patterns of GO, SnO\(_2\)-only and SnO\(_2\)-RGO hybrid. GO displays an intense peak at around \(2\theta = 10.9^\circ\), which corresponds to the (002) reflection of the stacked GO nanosheets [40]. It can be observed that the SnO\(_2\)-only sample shows broad and weak peaks ((110), (101), (200), (211) and (112)), which can be indexed to a tetragonal-structured SnO\(_2\) with poor crystallinity [41]. It is well known that after the reduction process, the diffraction peak of the GO shifts to around \(2\theta = 24.5^\circ\). This peak at \(2\theta = 24.5^\circ\) cannot be observed in the XRD pattern of the hybrid because this peak will be overlapped with the SnO\(_2\) peak (110). Another noticeable feature in the XRD pattern of SnO\(_2\)-RGO is that the SnO\(_2\) in the hybrid shows narrow and strong peaks, which can be assigned to a tetragonal structure (JCPDS card no. 41-1445), indicating an improved crystallinity of SnO\(_2\) and larger
average crystal size [42]. This improvement in the crystallinity is often observed in nanocarbon-metal oxide materials and is attributed to a heat-sink effect in which the nanocarbon facilitates crystallization via heat transfer [43].

The results of the XRD analysis were further confirmed by characterizing the samples using XPS (Fig. 2b), ATR-FTIR (Fig. 3a) and Raman spectroscopy (Fig. 3b). It can be clearly observed from the Raman spectra of the SnO$_2$-RGO hybrid (Fig. 3b) that the $I_D/I_G$ ratio of RGO increased compared to that of the GO. This increase in the $I_D/I_G$ ratio can be attributed to the defects caused during reduction of GO [27]. Moreover, it should be noted that in the XPS survey spectra, negligible peaks (Cl 2p) can be found in the SnO$_2$-based samples, which could be attributed to the unreacted Cl$^-$ of SnCl$_2$·2H$_2$O. Additionally, Auger and EDX elemental analysis were carried out on selected area of SEM images of the SnO$_2$-RGO hybrid and reveal small amount of chlorine remaining in the sample (see Fig. S2). These results of Auger and EDX spectroscopies were in good agreement with the XPS and may explain the sample crystallinity.

To study the influence of RGO on the efficiency of PV cells, DSSCs were fabricated using six photoanodes of different RGO content in the hybrid and were evaluated using simulated AM1.5 sunlight with an output power of 100 mW cm$^{-2}$. Notably, for the fabrication of DSSCs, the photoanodes were immersed in a TiCl$_4$ aqueous solution before they were soaked in the dye solution. This process is a commonly followed strategy to deposit a thin layer of TiO$_2$ over SnO$_2$ (SnO$_2$-RGO in our case) which can improve the $V_{oc}$ of the SnO$_2$-based DSSCs [18, 44-46]. Therefore, the photoanodes were denoted as “TiO$_2$-SnO$_2$-RGO (X)”, where the value of X indicates the weight concentration (wt%) of RGO in the hybrid. For example, the photoanode film prepared with 0.2 wt% RGO is denoted “TiO$_2$-SnO$_2$-RGO (0.2)”.

The photocurrent density–voltage ($J$–$V$) characteristics of the DSSCs assembled with these photoanodes are shown in Fig. 4a and the corresponding PV parameters have been summarized in Table 1. The control DSSC device (TiO$_2$-SnO$_2$-RGO (0)) fabricated based on SnO$_2$ photoanode without RGO showed an average PCE ($\eta$) of 1.28 ± 0.52% with a short-circuit current ($J_{sc}$) value of 4.78 ± 0.95 mA cm$^{-2}$ and $V_{oc}$ of 0.64 ± 0.01V which are typical values for such cells [12, 18].
It can be seen from Table 1 that from TiO$_2$-SnO$_2$-RGO (0) to TiO$_2$-SnO$_2$-RGO (0.7) (increasing RGO content), the $J_{sc}$ value increases from $4.78 \pm 0.95$ to $10.23 \pm 0.88$ mA cm$^{-2}$. We hypothesize that this increase in the $J_{sc}$ is due to the improved dye loading into the film and enhanced electron transfer within the photoanode [22, 27, 28]. In order to confirm our hypothesis, we fabricated SnO$_2$ films (Fig. S3) with different RGO content and investigated the dye adsorption capability of the films. No treatment with TiCl$_4$ solution was done to allow the effect of RGO in the SnO$_2$ film on the extent of dye adsorption to be probed without any interference. As shown in Fig. S3, the films after dye adsorption and also the solutions after subsequent desorption of the dye molecules using NaOH show that the dye adsorption of the SnO$_2$ films was significantly improved by incorporating RGO. Moreover, UV-vis spectra in Fig. 4b show the absorbance of dye desorbed from the films and shows that dye adsorption increases with increasing RGO concentration in the hybrid. This improvement in the dye adsorption is most likely due to a better matching of the molecular nature of the N719 dye and the chemical nature of the hybrid. N719 has both polar groups and aromatic regions. Since our RGO was derived from GO, some functional groups (–OH, –COOH etc.) would remain on the surface of RGO due to the partial reduction and these would interact with the polar groups on N719. These functional groups may be playing an important role in the dye adsorption [21]. SnO$_2$ would also interact with these polar groups. The introduction of the RGO provides some aromatic nature to the hybrid and one can speculate that this will create polar and aromatic regions in close proximity and will further enhance dye adsorption. Additionally the high-surface area of RGO may contribute to the adsorption of the dye [28]. Interestingly, the dye adsorption of the film with the highest RGO content (4.75 wt%) is starting to saturate, indicating that adding more RGO into the film would likely not lead to significant further increases in dye adsorption (see Fig. S4).

To determine the mechanism for the improved $J_{sc}$ value, the resistivity ($R_s$) of the TiCl$_4$ treated SnO$_2$ film without and with 0.45 wt% RGO was measured using a four point probe. The same film thickness on a glass substrate was obtained using the doctor blade method (see experimental details). The film without RGO shows a $R_s$ of $4.51 \times 10^6$ Ω/□, while the RGO incorporated film exhibits a comparatively low $R_s$ ($1.81 \times 10^6$ Ω/□) (see Table S1). The decrease in the $R_s$ (nearly 3-fold) of the film with RGO is due to the fact that high conductivity of the RGO in the hybrid reduces the interfacial resistance between SnO$_2$. In addition, the measured series resistance ($R_{series}$) of the TiO$_2$-SnO$_2$-RGO (0.45) based DSSC was 97.9 Ω, which was ~1.7-fold lower than that of the control cell (Table S1). On the basis
of these results, it is clear that the presence of RGO accelerated electron transport process within the photoanode and suppressed the charge recombination of the cells; thus significantly enhancing the $\eta$ [21, 22, 28].

However, although TiO$_2$-SnO$_2$-RGO (0.7) based cell showed the highest $J_{sc}$ (10.95 mA cm$^{-2}$), the measured average $\eta$ (2.08 ± 0.17%) was not the best observed, despite the films having high dye adsorption. When the RGO concentration in the hybrid further increased to 1.2 wt% and 4.75 wt%, a significant drop in the $J_{sc}$ value and $V_{oc}$ was observed for the TiO$_2$-SnO$_2$-RGO (1.2) and TiO$_2$-SnO$_2$-RGO (4.75) based DSSCs, thus resulting in very poor efficiencies. We attribute this $\eta$ decrease of the DSSCs with higher RGO loading to (i) opacity of the film (see films before dye adsorption in Fig. S3) reducing light absorption and (ii) high catalytic property of RGO, which has been shown to limit the continuous electron transfer at the photoanode [2, 21, 47].

It is well established that although carbon materials can facilitate electron transport in the DSSC, the catalytic activity of carbon materials toward reduction of the electrolyte causes significant charge recombination at the interface of the photoanode and electrolyte (since this reaction should only occur at the cathode) if too high concentration of carbon is used [2]. Fig. 4c shows the dark $J$–$V$ characteristics of DSSCs fabricated without and with RGO in the SnO$_2$ photoanodes. It is known that the magnitude and onset of the dark current indicates the level of charge recombination between the electrons from the dye excitation process and the I$_3^-$ ions in the electrolyte [48]. It can be seen that the dark current onset shifted to a lower potential after adding a small amount of RGO into the SnO$_2$ photoanodes. This is known to be due to the increased charge recombination rate of the DSSCs caused by the reaction between the RGO and electrolyte. Therefore, at a given voltage, the dark current increased when the RGO was added into the SnO$_2$ photoanode of DSSC. Our finding is in line with similar report of adding carbon powders into TiO$_2$ photoanodes [48].

Indeed, the highest $\eta$ (3.16%) with an average $\eta$ of 2.94 ± 0.24% was achieved for the device based on TiO$_2$-SnO$_2$-RGO (0.45). In the TiO$_2$-SnO$_2$-RGO based DSSC, the TiO$_2$ can act as a barrier layer reducing the contact of RGO with the electrolyte and therefore reducing the likelihood of RGO catalyzing recombination at the photoanode. Taking into account the TiO$_2$ deposition process (dip coating) which unlikely to achieve 100% coverage, we speculate that with higher RGO content the net amount of RGO in contact with the electrolyte will increase
accordingly. Moreover, we fabricated SnO$_2$ and SnO$_2$-RGO photoanodes based DSSCs without TiCl$_4$ treatment and their PV results have been plotted in Fig. S5a. The efficiencies of these DSSCs were \(~2\)-fold lower than those of the devices fabricated with TiCl$_4$ treatment, confirming that the use of TiCl$_4$ treatment is a vital method to enhance the cell performance in SnO$_2$ photoanode DSSCs.

It can be seen from Table 1 that all parameters of DSSC fabricated with SnO$_2$ photoanodes increased after incorporating 0.45 wt% RGO. The calculated $\eta$ enhancement of TiO$_2$-SnO$_2$-RGO (0.45) photoanode based device was impressive (91.5%) as compared to the control cell especially in light of the fact that a very small amount of RGO is required to realise these large improvements in efficiency. This photoanode (TiO$_2$-SnO$_2$-RGO (0.45)) was chosen for further investigation to fully understand the role of RGO in the DSSC.

IPCE spectra offer important information on the light harvesting efficiency which is mainly determined by the absorption of light by the dye molecules at the photoanode and electron transport processes. The IPCE spectra of the DSSCs with and without RGO in the photoanode are illustrated in Fig. 4d. It should be noted that the IPCE spectra of the DSSCs were characterized after the devices were aged for approximately 10 days. The IPCE of the TiO$_2$-SnO$_2$-RGO (0.45) photoanode based device is higher than that of the control DSSC over the entire wavelength region. The lack of wavelength dependence indicates that the addition of RGO into the SnO$_2$ photoanode improves the DSSC performance without altering the internal mechanism, likely by enhancing electron transfer rate and increasing dye adsorption onto the photoanode.

As discussed earlier, RGO in the hybrid ensures rapid electron transport process (Fig. 5a) and significantly enhances the $J_{sc}$ value of the DSSC. Importantly, it can be expected that incorporation of RGO in the SnO$_2$ photoanode would improve the DSSC performance owing to presence of suitable energy levels. Fig. 5b shows an energy level diagram for the TiCl$_4$ treated SnO$_2$ photoanode with RGO. Since a thin TiO$_2$ layer was deposited on the FTO and on the SnO$_2$ or SnO$_2$-RGO layers by TiCl$_4$ treatment, it is reasonable to include the energy level of TiO$_2$ in this diagram. The red arrow in Fig. 5b represents the fact that the electron transfer from the conduction band of SnO$_2$ to that of TiO$_2$ is not possible due to their mismatching band energy levels. As the TiO$_2$ coverage on the FTO is incomplete (not 100%), both SnO$_2$ and TiO$_2$ are in contact with the FTO and hence electron transfer from both the
SnO₂ and TiO₂ to the FTO is still feasible. The results from Fig. S6 and S7 show that despite the fact that the TiO₂ on the FTO is very thin, it does make a contribution to the current and voltage of the cell and as such is important to show. Since the energy level of RGO (-4.40 eV) lies between the conduction band of TiO₂ (-4.26 eV) and SnO₂ (-4.56 eV), the electrons can be rapidly transferred stepwise from the TiO₂ to the SnO₂ conduction band (see Fig. 5b) [18, 28]. Here RGO can act as a bridge between TiO₂ and SnO₂. This effective electron transfer would likely reduce the charge recombination of the cell, thus improves the performance.

Finally, the PV parameters of our best-performing cells have been compared with values reported in the literature for other DSSCs with SnO₂ based photoanodes. Table 2 summarizes the PV parameters such as $J_{sc}$, $V_{oc}$, FF and $\eta$ of DSSC devices fabricated with various SnO₂ structures based photoanodes and our best performing cells. It can be observed from Table 2 that the efficiency observed for our DSSC fabricated with SnO₂-RGO photoanode is comparable or higher than those achieved by other 1D and 3D SnO₂ structured photoanode films. Therefore, this indicates that the incorporation of graphene structures into SnO₂ photoanode is an effective strategy to achieve high efficiency DSSCs.

4. Conclusion
In summary, the successful application of RGO structures in 1D SnO₂ micro-rod based photoanodes for DSSCs has been demonstrated. Herein we show that the application of RGO overcomes the major shortcoming of SnO₂ when applied as a DSSC photoanode, namely poor dye adsorption. In addition, owing to its suitable energy levels and excellent conductivity, RGO significantly improved the electron transport rate in the cells. Importantly, PCE ($\eta$) of the DSSC was significantly improved to 3.16% by incorporating a very small amount of RGO into the photoanode, demonstrating a ~91.5% enhancement in the efficiency when compared to SnO₂-only photoanode based DSSC (1.65%).

**Fig. S1.** SEM image and EDX elemental analysis (inset) of SnCl₂·2H₂O sample (used as the starting material).

**Fig. S2.** (a) Auger and (b) EDX elemental analysis on the selected area (highlighted by red rectangle in (a) and circle in (b)) of the corresponding SEM images of SnO₂-RGO hybrid, as shown in the inset in b).
**Fig. S3.** Dye adsorption capability of the films (SnO$_2$-RGO (X)) with different RGO content. In SnO$_2$-RGO (X), the value of X indicates the weight concentration (wt%) of RGO in the hybrid. For instance, the concentration of RGO in the SnO$_2$-RGO (0.45) was 0.45 wt%.

**Fig. S4.** The absorbance of these solutions at a wavelength of 520 nm.
Fig. S5a shows the J–V curves of DSSCs assembled with different RGO in the SnO$_2$ photoanodes (without any TiCl$_4$ treatment on the photoanode). The overall trend in the efficiency changes (increased after adding appropriate amount of RGO into the SnO$_2$ and decreased at too high concentration of RGO in the photoanodes) of DSSCs without and with TiCl$_4$ treatment was very similar, demonstrating that adding RGO into SnO$_2$ photoanode can enhance the PV efficiency, regardless of additional TiCl$_4$ treatment. A possible energy diagram for SnO$_2$-RGO photoanode based DSSC is shown in Fig. S5b. In this device structure, RGO enhances the electron transport rate and can also act as a bridge between dye and SnO$_2$. Notably, the efficiency of our SnO$_2$-only based DSSC was within the range (ranging from 0.6% to 1.0%) of previously reported values [1-3].

**Fig. S5.** (a) J–V curves of DSSCs fabricated with different RGO content in the SnO$_2$ photoanode without the TiO$_2$ blocking layer and (b) an energy level diagram for the SnO$_2$-RGO photoanode without any TiO$_2$ blocking layer.

It should be noted that TiO$_2$ was formed on the FTO by TiCl$_4$ treatment. However, it is well established that the TiO$_2$ does not completely cover FTO which makes electron transfer process possible between SnO$_2$ and FTO [4–7]. In order to prove that the coverage of TiO$_2$ during from TiCl$_4$ treatment on FTO is not 100%, DSSCs with a structure FTO/TiO$_2$/SnO$_2$/dye/electrolyte/Pt/FTO (without the second TiCl$_4$ treatment) were fabricated and their J-V characteristics are illustrated in Fig. S6a. It is reasonable to
expect that the DSSC fabricated with such structure cannot work if the TiO₂ completely (100%) covered the FTO because the conduction band of TiO₂ (-4.25 eV) is higher than that of SnO₂ (-4.56 eV) and thus energy transfer from the SnO₂ to the FTO through TiO₂ layer would not be feasible (see Fig. S6b). Interestingly, the fabricated DSSC exhibited a good efficiency (1.17%) with increased $V_{oc}$ value, as compared to SnO₂ photoanode based DSSC without any blocking layer TiCl₄ treatment. Cells with the TiO₂ blocking layer only and SnO₂–free photoanode give a very poor performance (see Fig. S7). The improvement in efficiency for the cell of Fig. S6 compared to the cell without graphene of Fig. S5 means that while the TiO₂ on the FTO must play a small role in the cell, the SnO₂ must also be in direct contact with the FTO and able to transfer electrons. This clearly show the thin TiO₂ layer does not cover the FTO completely and electron transfer from both oxides must occur. The incomplete coverage and thinness of TiO₂ on the FTO means the majority of the photovoltaic performance is from the SnO₂ layer.

Fig. S6. (a) J–V curves of DSSC device assembled with the photoanode structure of FTO/thin TiO₂/SnO₂/dye (without second TiCl₄ treatment). Inset shows the device structure. (b) A possible energy level diagram for this DSSC photoanode.

In addition, only TiCl₄ treated FTO as a photoanode based DSSC was fabricated and its performance is depicted in Fig. S7. For this experiment, the cleaned FTO was immersed in a 40 mM TiCl₄ aqueous
solution at 70°C for 30 min, followed by drying with N$_2$ gas and annealing at 450°C for 30 min. After cooling to room temperature, second TiCl$_4$ treatment was performed in a same manner. Finally the film was sintered at 450°C for 30 min and then exposed the dye solution as before. As a result, the fabricated cell showed high $V_{oc}$ value, but its PCE was very poor (0.13%). This result is reasonable since the $V_{oc}$ parameter is determined by the energy level difference between the conduction band of semiconducting photoanode material (TiO$_2$ here in this device) and the potential energy of the electrolyte. The very low $J_{sc}$ value of this cell is due to the insufficient dye-loading into the photoanode film as only very thin TiO$_2$ and low surface area layer is formed on the FTO. A poor fill factor value could also be associated with the incomplete coverage of TiO$_2$ on the FTO. These results again show that the SnO$_2$ is the main active element of the these photoanodes.

![J-V curve of DSSC](image)

**Fig. S7.** J–V curves of DSSC fabricated with thin TiO$_2$ layers on FTO as a photoanode. Notably, TiO$_2$ layers were formed on the FTO by 2 times TiCl$_4$ treatment as was done for the normal device structure. Inset shows the device structure.
