## ABSTRACT

**Introduction:** In the SPIRIT-H2H (ClinicalTrials.gov: NCT03151551) trial in biologic-naïve patients with active psoriatic arthritis (PsA), ixekizumab (IXE) was superior to adalimumab

(ADA) at week 24 in terms of achieving a combined endpoint of  $\geq 50\%$  improved response in the American College of Rheumatology scale score (ACR50) and 100% improvement in the Psoriasis Areas and Severity Index (PASI100), and was non-inferior in terms of achieving ACR50. IXE resulted in similar improvements of PsA manifestations irrespective of the use of concomitant conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), while ADA response was higher with concomitant csDMARD use. The aim of this study was to determine the efficacy and safety of treatment with IXE and ADA with or without methotrexate (MTX), the most commonly use csDMARD, through week 52 in patients with PsA.

**Methods:** In the open-label, rater-blinded, head-to-head SPIRIT-H2H trial, randomization of patients was stratified by concomitant use of csDMARD and moderate-to-severe plaque psoriasis involvement. In the post-hoc subgroup analysis presented here, subgroups were defined as with/without concomitant MTX use at baseline. Treatment group effects within subgroups were tested using Fisher's exact test. Missing data were imputed using non-responder imputation.

**Results:** By week 52, IXE provided similar improvements in the combined ACR50 and PASI100 endpoint, ACR50, and other PsA-related domains regardless of whether IXE was used with or without MTX, while ADA efficacy

appeared to be improved with concomitant MTX use. When used without concomitant MTX, IXE resulted in significantly higher response versus ADA in terms of the combined ACR50 and PASI100 ( $p = 0.002$ ) endpoint, minimal disease activity ( $p = 0.016$ ), and very low disease activity ( $p = 0.037$ ). The safety of both agents was consistent with their known safety profiles regardless of concomitant MTX use.

**Conclusion:** In PsA patients with inadequate control of the disease, IXE delivers consistent efficacy in several clinical domains of the disease regardless of concomitant MTX use. The efficacy of ADA is increased by the concomitant use of MTX. These findings can inform treatment decisions when considering the need for concomitant MTX use with IXE or ADA at initiation or for long-term maintenance.

**Keywords:** Adalimumab; csDMARD; Ixekizumab; Methotrexate; Psoriatic arthritis

### Key Summary Points

#### Why carry out this study?

Limited evidence is currently available on the impact of concomitant use of methotrexate (MTX) on the efficacy and safety of biologic disease-modifying anti-rheumatic drugs (bDMARDs) approved for the treatment of patients with psoriatic arthritis (PsA).

The aim of this study was to investigate the efficacy and safety of two bDMARDs, ixekizumab and adalimumab, with or without MTX through week 52 in patients with PsA.

#### What was learned from the study?

The results of this study suggest that ixekizumab demonstrated identical efficacy in joint endpoints with or without concomitant MTX, while adalimumab efficacy appears to increase with the concomitant use of MTX.

The safety of both agents was consistent with their known safety profiles regardless of concomitant MTX use.

The results of this study inform evidence-based treatment decisions when considering concomitant MTX use when prescribing ixekizumab or adalimumab for patients with PsA.

## DIGITAL FEATURES

This article is published with digital features, including a summary slide, to facilitate understanding of the article. To view digital features for this article go to <https://doi.org/10.6084/m9.figshare.13135763>.

## INTRODUCTION

Psoriatic arthritis (PsA) is a heterogeneous inflammatory disease [1–3] that is characterized by the presence of arthritis and often also by other musculoskeletal manifestations, including enthesitis, dactylitis, and/or axial involvement, potentially resulting in joint damage, impaired physical function, and reduced quality of life (QoL). In addition to joint symptoms, PsA is often associated with extra-articular manifestations, including skin and nail psoriasis that contribute to the increased burden of illness and the reduced QoL [1, 4].

Treatment for PsA remains challenging due to the heterogeneity of the disease. The European League Against Rheumatism (EULAR) 2019 recommendations include the initial use of non-steroidal anti-inflammatory drugs for musculoskeletal manifestations followed by single conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), such as methotrexate (MTX), which is the most frequently used csDMARD in PsA [5, 6]. While data on the efficacy of MTX in monotherapy are controversial [7], recent studies, such as the

TICOPA and PsA-SEAM trials, reveal a high level of efficacy [8, 9], and some even interpret the efficacy as being similar to that of a tumor necrosis factor inhibitor (TNFi) [10].

The beneficial effect of the concomitant use of MTX with a biologic DMARD (bDMARD) in patients with PsA is still being debated [11]. The EULAR recommends using bDMARDs, such as TNFi and anti-interleukin (IL)-12/23 or IL-17A antagonists, as add-on to csDMARD or as a monotherapy for PsA patients with inadequate response to csDMARDs. There is limited evidence to support the clinical decision of whether to use concomitant MTX with bDMARDs from the beginning of a patient's care or whether to maintain or stop concomitant MTX in patients with PsA with a good clinical response [12]. Although the TEMPO, PREMIER, GO-AFTER, SURPRISE and ACT-RAY studies conducted in patients with rheumatoid arthritis have shown better efficacy with bDMARDs when combined with MTX compared with bDMARD monotherapy [13–17], data comparing combination therapy with bDMARD monotherapy in patients with PsA are limited and inconclusive [9].

Ixekizumab (IXE) is a high-affinity monoclonal antibody that selectively targets IL-17A and is approved for the treatment of moderate-to-severe plaque psoriasis (PsO), PsA, ankylosing spondylitis, non-radiographic axial spondylarthritis, and pediatric PsO [18–21]. SPIRIT-H2H (ClinicalTrials.gov: NCT03151551) is a 52-week trial evaluating the efficacy and safety of IXE versus adalimumab (ADA), a TNFi, in bDMARD-naïve patients with active PsA and inadequate response to csDMARDs. IXE was found to be superior to ADA at week 24 for the combined improvement in joint and skin disease (as measured by the percentage of patients achieving  $\geq 50\%$  improvement in the American College of Rheumatology scale score [ACR50] and 100% improvement from baseline in the Psoriasis Areas and Severity Index rating score [PASI100]) [22]. Furthermore, IXE achieved the major secondary endpoints at week 24 of non-inferiority of IXE versus ADA for ACR50 responses and superiority of IXE versus ADA for PASI100 response. Also, a greater proportion of patients receiving IXE compared

with ADA achieved the combined endpoints of ACR50 and PASI100 response at week 52. For other musculoskeletal-related domains, the responses observed at week 24 were maintained until week 52. IXE efficacy on the combined ACR50 and PASI100 response, as well as on separately assessed ACR50 and PASI100 responses, were similar with or without csDMARDs, while response to ADA seemed better with concomitant csDMARD use [23].

The objective of the current analysis is to evaluate the efficacy of IXE and ADA through 52 weeks of treatment when used with and without concomitant MTX.

## METHODS

### Participants

Inclusion criteria have been detailed in a previous publication [22]. Briefly, eligible patients were aged  $\geq 18$  years, had an established diagnosis of PsA for at least 6 months, fulfilled the CIASsification for Psoriatic ARthritis (CASPAR) criteria, and had active PsA defined as at least 3/66 swollen and at least 3/68 tender joints. Patients were also required to have active PsO affecting  $\geq 3\%$  of body surface area (BSA), had previous inadequate response to  $\geq 1$  csDMARD, and had no prior treatment with any bDMARD or targeted synthetic DMARDs.

### Study Design and Treatment

The SPIRIT-H2H study design has been described in a previous publication [22]. Briefly, it is a phase 3b/4, multicenter, randomized, open-label, parallel-group (head-to-head) trial with a 52-week duration with rater-blinded outcome assessments evaluating the efficacy and safety of IXE versus ADA in bDMARD-naïve patients with PsA and active PsO who had previous history of inadequate response to csDMARDs. During a 52-week open-label treatment period (weeks 0–52), patients were randomly assigned in a 1:1 ratio to receive subcutaneous injections of either IXE 80 mg every 4 weeks starting at week 4 or a 40-mg starting dose of ADA at

randomization (week 0) followed by 40 mg ADA every 2 weeks starting at week 2 (unless they met the criteria for moderate-to-severe PsO). Patients with moderate-to-severe PsO received either 80 mg IXE every 2 weeks from week 2 to week 12, followed by 80 mg IXE every 4 weeks or an 80 mg starting dose of ADA (two injections) at week 0, followed by 40 mg ADA every 2 weeks starting at week 1. For all patients assigned to the IXE treatment arm, the starting dose was 160 mg (two 80 mg subcutaneous injections) administered at randomization. Randomization was stratified by concomitant csDMARD use at baseline and moderate-to-severe PsO involvement (PASI  $\geq$  12, BSA  $\geq$  10% and Static Physician's Global Assessment [sPGA]  $\geq$  3). MTX, when included, must have been used for at least 12 weeks and as a stable dose for at least 8 weeks prior to randomization. The permitted MTX dose was 10–25 mg/week oral or parenteral. Changes in MTX background use were not permitted during the first 24 weeks of the study period except for safety reasons. Adjustment in MTX background use was allowed after week 24.

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committees at all sites where these studies were conducted and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the studies. The study protocol was approved by the ethical review board of all participating centers prior to the start of study-related procedures (see Electronic Supplementary Material [ESM] for the full list of ethics committees). The main ethics committee was Whipps Cross University Hospital, London, UK (registration no. 17/LO/0794).

### Efficacy and Safety Endpoints

Endpoints were assessed in subgroups defined by the presence or absence of concomitant MTX use at baseline (post-hoc subgroups). The primary endpoint was the proportion of patients

who achieved combined ACR50 and PASI100 responses at week 24. After the week-24 database lock and initial analysis run, a medical inconsistency in baseline PASI data was identified. Although nine patients were assessed as PASI = 0 at baseline (including 5 patients with MTX at baseline and 4 patients without MTX at baseline), those patients fulfilled the criteria for having psoriasis as assessed by a BSA  $\geq$  3%. Therefore, those patients were judged as being PASI100 responders if they achieved an absolute PASI = 0 and BSA = 0 at post-baseline visits. Additional prespecified outcomes assessed the proportion of patients achieving 20, 50 or 70% improvement from baseline in the ACR scale score (ACR20/50/70, respectively); resolution of enthesitis as measured by the Spondyloarthritis Research Consortium of Canada Enthesitis Index (SPARCC Enthesitis Index = 0) or Leeds Enthesitis Index (LEI = 0) among patients with enthesitis at baseline (SPARCC Enthesitis Index > 0 or LEI > 0, respectively); resolution of dactylitis as measured by the Leeds Dactylitis Index–Basic (LDI-B = 0) among patients with dactylitis at baseline (LDI-B > 0); a modified Composite Psoriatic Disease Activity Index (mCPDAI)  $\leq$  5 (low disease activity or remission);  $\geq$  75%,  $\geq$  90%, or  $\geq$  100% improvement from baseline in PASI (PASI75/90/100, respectively); resolution of fingernail psoriasis (Nail Psoriasis Area and Severity Index [NAPSI] fingernails = 0); PsA Dermatology Life Quality Index score of 0 or 1 (DLQI [0, 1]); and minimal disease activity (MDA) assessed by 18 enthesal points (MDA was achieved if patients fulfilled 5 of 7 outcome measures: tender joint count  $\leq$  1; swollen joint count  $\leq$  1; PASI total score  $\leq$  1 or BSA  $\leq$  3; patient pain visual analog scale (VAS) score of  $\leq$  15; patient global assessment VAS score of  $\leq$  20; Health Assessment Questionnaire–Disability Index (HAQ-DI) score of  $\leq$  0.5; and tender enthesal points  $\leq$  1). Other outcomes included the proportion of patients achieving Disease Activity in Psoriatic Arthritis (DAPSA) score  $\leq$  4 (remission) and DAPSA  $\leq$  14 (low disease activity or remission) and very low disease activity (VLDA).

Treatment-emergent adverse events (TEAEs) were defined as an event that first occurred or worsened in severity after baseline (first dose),

on or before the last day of the treatment period. General safety included TEAEs, serious adverse events (SAEs), deaths, and discontinuations due to adverse events (AEs). AEs of special interest included infections, serious infections, malignancies, major adverse cerebrocardiovascular events (MACE), inflammatory bowel disease, injection-site reactions, depression, hepatic laboratory changes, cytopenia, and neutropenia.

### Efficacy and Safety Analyses

Post-hoc analyses of efficacy and QoL outcomes were performed through week 52 in the intent-to-treat population, consisting of all randomized patients according to treatment assigned at week 0. For the efficacy analysis, treatment group differences were evaluated within each MTX subgroup using Fisher's exact test. Missing data were imputed using non-responder imputation. Any  $p$  value below 0.05 was considered to be statistically significant.

The study was not powered to perform statistical comparison of safety data between two treatment arms. Descriptive statistics were performed on the safety population, defined as all randomized patients who received  $\geq 1$  dose of the study treatment.

## RESULTS

### Participants

Patient demographic and baseline characteristics are provided in Table 1. Of the 566 patients (intent-to-treat population) with PsA selected for this post-hoc analysis, 283 patients received IXE (116 without MTX and 167 with MTX) and 283 patients received ADA (114 without MTX and 169 with MTX). Among patients taking MTX, 9.0% (15/167) and 7.1% (12/169) treated with IXE and ADA, respectively, were taking an additional csDMARD (leflunomide, sulfasalazine, or cyclosporine). Baseline demographics and disease characteristics were well balanced between treatment groups.

## Efficacy

### Major Outcomes

Efficacy outcomes at week 52 are summarized in Table 2. At week 52, combined ACR50 and PASI100 response (primary endpoint) with IXE was similar regardless of whether it was used with (38.9%) or without (39.7%) MTX. ADA response was numerically higher when used with MTX (30.2%) than without MTX (20.2%). For patients not taking MTX, significantly ( $p = 0.002$ ) more patients achieved the primary endpoint with IXE (39.7%) than with ADA (20.2%); significant differences were observed as early as week 8 (Fig. 1a). For patients taking concomitant MTX, a numerically higher proportion of patients treated with IXE achieved the primary endpoint compared with those taking ADA (IXE 38.9%, ADA 30.2%,  $p = 0.108$ ; Fig. 1b). ACR50 response was similar when IXE was used with (47.9%) or without (52.6%) MTX, while ADA response was numerically higher when the treatment was used with (56.2%) than without (40.4%) MTX (Table 2). There were no statistically significant differences in ACR50 response between treatment arms when used with or without MTX throughout the 52 weeks observed (Fig. 1c, d).

### PsA Treatment Targets According to Treat-to-Target

At week 52, MDA response in patients treated with IXE was similar regardless of whether it was used with (46.7%) or without (48.3%) MTX, while ADA response was numerically higher when used with MTX (46.7%) than without MTX (32.5%). When used without MTX, significantly more patients achieved MDA at week 52 in the IXE (48.3%) versus ADA (32.5%) group ( $p = 0.016$ ) (Table 2; Fig. 2a). Among patients using MTX, similar responses in terms of MDA were observed between treatment groups at week 52 (Fig. 2b). VLDA response with IXE was numerically lower when used with MTX (20.4%) than without MTX (27.6%), whereas ADA efficacy of VLDA was numerically higher with MTX (21.3%) than without MTX (15.8%). For patients not taking MTX, significantly ( $p = 0.037$ ) more patients achieved VLDA with

IXE (27.6%) than with ADA (15.8%). Among patients taking MTX, there were no significant differences in VLDA between IXE (20.4%) and ADA (21.3%) at week 52. Among patients not using MTX, significantly ( $p = 0.017$ ) more patients achieved low disease activity or remission according to DAPSA ( $\leq 14$ ) at week 52 in the IXE (62.9%) versus the ADA (46.5%) group (ESM Table 1), whereas when used with MTX, there were no statistical differences between IXE and ADA in DAPSA remission ( $\leq 4$ ) (Table 2; Fig. 2c, d). There were no statistically significant differences in DAPSA  $\leq 4$  (Table 2; Fig. 2c, d) and DAPSA  $\leq 14$  responses at 52 weeks between treatment arms when used with MTX (ESM Table 1).

### Other Outcomes

Resolution of enthesitis (SPARCC enthesitis = 0) was similar with IXE and ADA regardless of whether they were used with or without MTX (Table 2). There were no statistically significant differences between IXE and ADA (with MTX/

without MTX) in SPARCC enthesitis Index = 0 from week 8 through week 52 (Fig. 3a, b).

### Nail Psoriasis Outcome

At week 52, IXE response on NAPSI fingernails = 0 was similar regardless of whether it was used with MTX (66.7%) or without MTX (68.7%), while ADA response was numerically higher when used with MTX (64.4%) than without MTX (51.3%) (Table 2). For patients not taking MTX, significantly ( $p = 0.035$ ) more patients achieved NAPSI = 0 response with IXE (68.7%) than with ADA (51.3%) at week 52 (Table 2).

### QoL Outcome and Physical Function

Responses for QoL and function outcomes were lower with IXE when it was used with MTX than when used without MTX, while ADA responses were numerically higher when used with MTX than when used without MTX (Table 2). At week 52, for patients not taking MTX, HAQ-DI  $\leq 0.5$  response was significantly

higher with IXE than with ADA (*p* = 0.026); statistically significant response was observed only at this timepoint.

## Safety

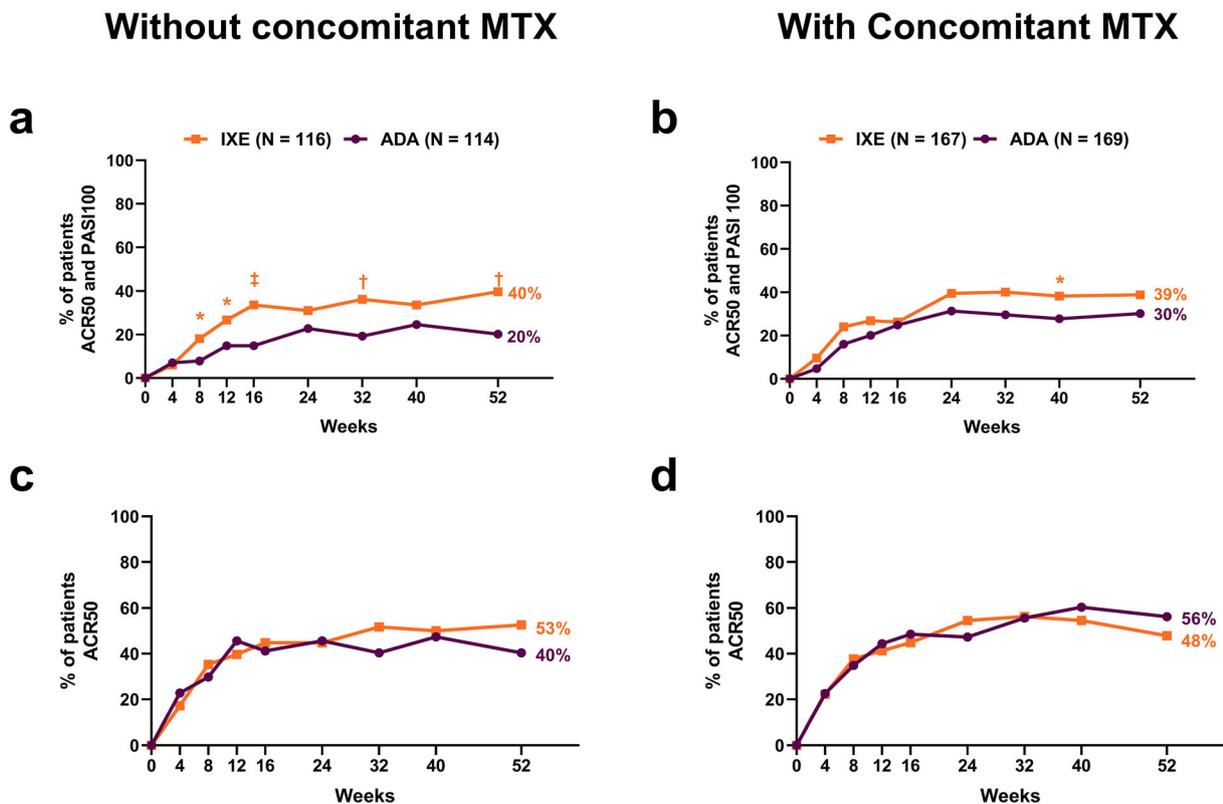

### General Safety

The overall safety of IXE and ADA was consistent with the known safety profile of both drugs (Table 3). The safety profile was consistent between subgroups who did or did not receive MTX for both IXE and ADA. Severe TEAEs, SAEs,

and discontinuations due to AEs were numerically lower in the IXE treatment group than in the ADA treatment group regardless of whether patients received MTX or not. No deaths occurred during the study.

### Adverse Events of Special Interest

Treatment-emergent adverse events of malignancies, MACE, IBD, injection site-reactions, depression, and neutropenia were generally similar in frequency with or without MTX for both treatment arms (IXE or ADA) (Table 3).

**Fig. 1** Clinical response rates for major outcomes through week 52 in the intent-to-treat population (nonresponder imputation). **a, b** Percentage of patients achieving the combined ACR50 and PASI100 endpoints. **c, d** Percentage of patients achieving ACR50. \*, †, ‡ Significant difference IXE vs. ADA at: \* $p < 0.05$ , and † $p \leq 0.01$ ; ‡ $p \leq 0.001$ ,

respectively. ACR50 50% improvement in the American College of Rheumatology scale score, PASI100 100% improvement (= disease clearance) in the Psoriasis Area and Severity Index score, ADA adalimumab, IXE ixekizumab, MTX methotrexate

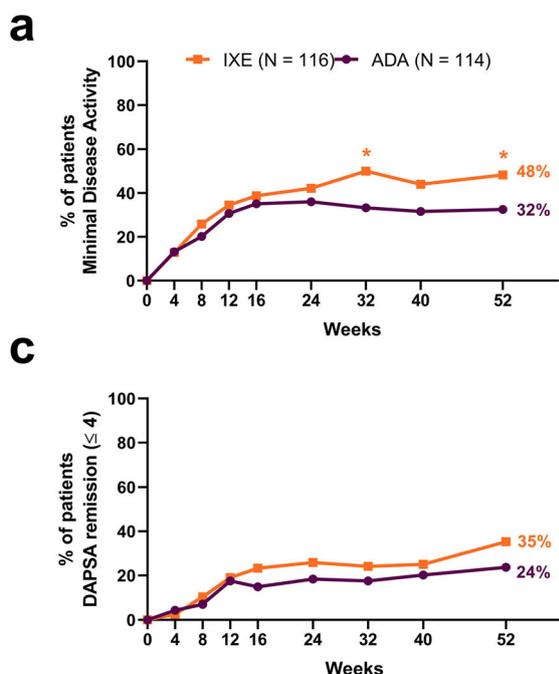

Numerically more abnormal liver function test values and cytopenia were reported with MTX than without MTX for both the IXE and ADA treatment arms. Numerically more infectious events were reported without MTX than with MTX.

## DISCUSSION

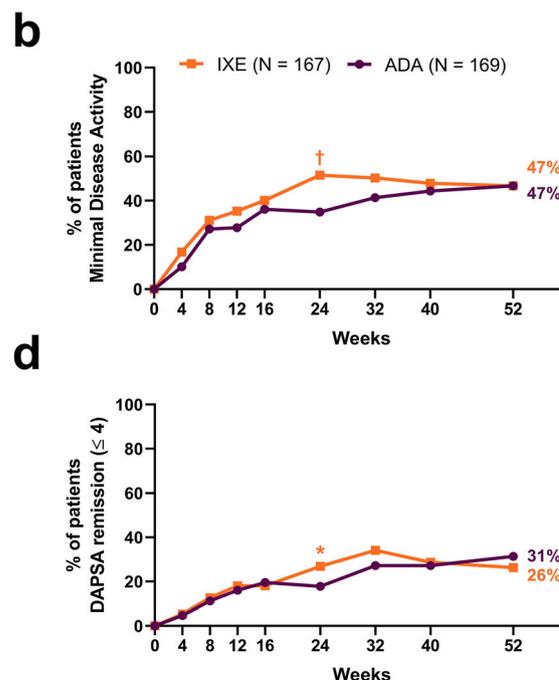

The results from the SPIRIT-H2H study at 52 weeks suggested that the efficacy of IXE is independent of MTX in terms of achieving optimal outcomes in patients with PsA. In contrast, ADA efficacy was found to be numerically better with concomitant MTX use than without MTX use. A similar pattern of responses

was observed with IXE and ADA when used with all csDMARDs (MTX, leflunomide, sulfasalazine, or cyclosporine) [23]. These results are relevant in clinical practice for informing treatment decisions for patients with PsA for whom MTX may be not recommended (those who have inadequate response or intolerance to MTX) as ADA seems to be less effective than IXE for the treatment of clinical manifestations of PsA in terms of the outcomes in patients who are not taking concomitant MTX. Although EULAR acknowledges there is no clear evidence that MTX in combination with bDMARD is more efficacious than bDMARD monotherapy, the organization recommends using concomitant MTX with bDMARD in patients already on MTX without signs of intolerance [5]. The

activity. **c, d** Percentage of patients achieving a DAPSA score  $\leq 4$  (remission). \*,†Significant difference IXE vs. ADA at: \* $p < 0.05$  and † $p \leq 0.01$ . DAPSA Disease Activity in Psoriatic Arthritis

findings from this analysis reported here can inform treatment decisions when considering concomitant MTX use with IXE or with ADA at initiation of treatment or for long-term maintenance.

The ADEPT study of ADA in patients with PsA found that ACR20, ACR50, and ACR70 responses were similar regardless of whether ADA was used with or without MTX [24, 25]. Our results showed ADA efficacy on treat-to-target endpoints (MDA and VLDA, as well as DAPSA low disease activity/remission), skin (PASI75/90/100), and QoL endpoints (DLQI [0,1]) was higher when used with MTX (Table 2; ESM Table 1). It has been shown that MTX in combination with ADA demonstrated better results on the PASI than ADA monotherapy in patients with moderate-to-severe PsO [26]. Since

skin outcomes are a component of the MDA score and DLQI (0,1), improvements in skin outcomes in the SPIRIT-H2H study with ADA in combination with MTX likely contributed to greater MDA and DLQI (0,1) results. However, neither the ADEPT nor the SPIRIT-H2H study were designed to compare ADA as monotherapy with ADA plus concomitant MTX use as a primary endpoint. Both IXE and ADA are approved for the treatment of PsA with or without MTX [21, 27].

In this subanalysis of the SPIRIT-H2H trial comparing the effects of IXE to ADA in patients with PsA who were bDMARD-naïve, we demonstrated that response to IXE without MTX was higher than the response to ADA without MTX for multiple joint and skin endpoints. The EXCEED study comparing secuk-

inumab safety and efficacy versus ADA without concomitant csDMARD use in patients with active PsA who were naïve to biologic therapy and intolerant or with inadequate response to csDMARD [28] failed to show the superiority of secukinumab versus ADA on ACR20 (primary endpoint). However, EXCEED reported a significantly higher response with secukinumab versus ADA in some joint and skin endpoints. The SPIRIT-H2H and the EXCEED studies support the role of IL-17A inhibitors for the treatment of patients with PsA.

The main strength of this analysis is the study design with a 52-week duration, which allows the evaluation of efficacy of IXE and ADA with concomitant use of MTX over a long treatment duration. Since randomization was stratified by csDMARD use, the subgroups were well balanced, enabling proper comparisons. This study design permits the use of concomitant MTX therapy and better reflects clinical practice for patients with PsA. In an era of tailored medicine, this information adds to the importance of providing flexible treatment strategies depending on the patient's preference and tolerance to MTX. A limitation of this post-

hoc analysis is the fact the SPIRIT-H2H study was not powered to evaluate the benefit of MTX in combination with a bDMARD, resulting in small sample sizes in each subgroup. The open-label study design increases the real-world clinical setting compared to double-blind trials. The double-blind study design would have increased the burden due to the number of injections per week and make the study not acceptable for patients. While the open-label design could have influenced patients' assessment outcomes, such as components of ACR measure, in the SPIRIT-H2H study, patients were treated equally regardless of which treatment they received, thereby minimizing the bias of patients' assessment outcomes.

Although the majority of patients enrolled in this study had polyarthritis, a similar finding was observed in other clinical trials in patients with PsA. Enrolled patients may not fully represent all PsA patients in daily real-world clinical practice (e.g., patients in this study predominantly had polyarthritis while in clinical practice patients mostly have oligoarticular involvement).

**Table 3** Safety outcomes at week 52

Safety outcomes	IXE treatment arm		ADA treatment arm

Unless otherwise indicated, values are presented as a number with the percentage (*n/N*) given in parentheses

*ALP* Alkaline phosphatase, *ALT* alanine aminotransferase, *AST* aspartate aminotransferase, *IBD* inflammatory bowel disease, *MACE* major adverse cardiovascular events, *n* number of patients in a group, *N* number of patients, *ULN* upper limit normal from performed laboratory reference ranges

<sup>a</sup> Severity of an adverse event is judged by patient or investigator

<sup>b</sup> Serious adverse event met the serious criteria of the International Council for Harmonization

<sup>c</sup> Two IBD events were reported in the IXE treatment group during the 0- to 24-week period but only 1 case was adjudicated as confirmed Crohn's disease. One event was reported as colitis ulcerative but was not adjudicated as confirmed ulcerative colitis [21]

<sup>d</sup> Liver function test values were calculated as percentages using the denominator total of 283 for both the IXE and ADA groups

<sup>e</sup> Post-baseline  $\geq$  3 ULN

<sup>f</sup> Post-baseline bilirubin  $\geq$  1.5 ULN; post-baseline ALP > 1.5 ULN

## CONCLUSION

Ixekizumab demonstrated similar efficacy across different domains of PsA regardless of whether it was used with or without MTX. As a clinical issue for rheumatologists, this raises the possibility that it may not be necessary to treat with patients currently taking or about to start IXE with concurrent MTX. In patients who did not receive MTX, IXE long-term efficacy was greater than that of ADA across multiple skin and musculoskeletal disease-specific outcomes. The safety of both agents was consistent with their known safety profile regardless of concomitant MTX use. The findings of this study increase awareness of current treatment options and inform evidence-based treatment decisions when considering concomitant MTX use when prescribing IXE or ADA for patients with PsA and active psoriatic skin disease.

## ACKNOWLEDGEMENTS

The authors thank the study participants, caregivers, and investigators.

**Funding.** This study and the journal's Rapid Service Fee were funded by Eli Lilly and Company, which contributed to study design, data collection, data analysis, data interpretation, manuscript preparation, and publication decisions.

**Medical Writing and Editorial Assistance.** Elsa Mevel, PhD and Cynthia R. Abbott who are employees of Eli Lilly provided writing and editorial assistance. Funding for this assistance was provided by Eli Lilly and Company.

**Authorship.** All named authors meet the International Committee of Medical Journal Editors (ICMJE) criteria for authorship for this article, had full access to all the data in this study, take responsibility for the integrity of data and accuracy of the data analysis, and have given their approval for this version to be published.

**Disclosures.** Josef S Smolen reports research grants from AbbVie, Astra-Zeneca, Janssen, Lilly, Merck Sharp & Dohme, Novartis, Pfizer, and Roche; and personal fees from AbbVie, Amgen, Astra-Zeneca, Astro, Bristol-Myers Squibb, Celgene, Celltrion, Chugai, Gilead, ILTOO, Janssen, Lilly, MSD, Novartis-Sandoz, Pfizer, Roche, Samsung, Sanofi, and UCB.
