Abstract

Carbonic anhydrase (CA) enzymes, specifically membrane-bound isoymes CA IX and CA XII, underpin a pH-regulating system that enables hypoxic tumor cell survival and proliferation. CA IX and XII are implicated as potential targets for the development of new hypoxic cancer therapies. To date only a few small molecules have been characterized in CA-relevant cell and animal model systems. In this paper we describe the development of a new class of carbohydrate-based small molecule CA inhibitors, many of which inhibit CA IX and XII within a narrow range of low nanomolar $K_i$ values (5.3-11.2 nM). We evaluate for the first time carbohydrate-based CA inhibitors in cell-based models that emulate the protective role of CA IX in an acidic tumor microenvironment. Our findings identified two inhibitors (compounds 5 and 17) that block CA IX-induced survival and have potential for development as in vivo cancer-cell selective inhibitors.
Background

Tumor cells alter their metabolism when in a low oxygen (hypoxic) microenvironment to survive, proliferate and metastasise. The hypoxia-inducible transcription factor (HIF-1) regulates gene expression of proteins that are responsible for alterations in hypoxic tumor cell metabolism – one core aspect of which is the shift from aerobic to fermentative glycolysis. Fermentative glycolysis leads to elevated lactic acid production, hence a drop in the intracellular pH (pHi) of hypoxic tumor cells is expected unless pH homeostasis is established. Carbonic anhydrase (CA, EC 4.2.1.1) enzymes, specifically isozymes CA IX and CA XII, have been shown to underpin a robust pH-regulating system by maintaining a pHi range compatible with cell viability and proliferation, while they contribute to the extracellular acidification of the tumor microenvironment. These enzymes confer a survival advantage to tumor cells growing in a hypoxic and acidic microenvironment. CAs catalyze the reversible hydration of carbon dioxide (CO₂) to generate a bicarbonate anion (HCO₃⁻) and a proton (H⁺). CA IX and XII differ from cytosolic CAs in that they are transmembrane proteins with an extracellular catalytic domain. A characterized role of CA IX and XII in cancer is the hydration of tumor cell generated CO₂, the net effect is to trap H⁺ extracellularly, lowering pH outside the cell (pHo) whilst maintaining normal pHᵢ. CA IX and XII expression is upregulated in a wide variety of human tumors under the control of HIF-1, CA IX is commonly absent in corresponding normal tissue (except the stomach and GI tract), while CA XII is expressed in a selection of normal tissues. The impact of modulating CA activity on tumor growth was recently affirmed in a set of in vivo studies in mice. These studies demonstrated that silencing of ca9 and ca12 genes using shRNA significantly reduced the rate of xenograft growth and this outcome was attributed to slowed proliferation in the absence of membrane-associated CAs. In humans, studies targeting CA IX-expressing cells using immunotherapy with the monoclonal antibody G250, have reached clinical trials for the treatment of patients with metastatic renal
cell carcinoma. Based on the in vivo mouse results using genetic silencing and success with immunotherapy in human cancer patients, the modulation of CA IX and XII with small molecule inhibitors represents a mechanistically novel opportunity with potential for anticancer therapy intervention. From the perspective of targeted cancer therapeutics, this hypothesis has generated scientific interest that so far remains to be comprehensively explored. To date only a few small molecules have been characterized in CA-relevant cell and animal model systems. CA inhibitors that incorporate a hydrophilic moiety such as a cationic pyridinium and ‘Cp*Ru(II)’ salts or carbohydrate moieties have been developed to have limited membrane permeability and so may better target CA IX and XII over CA II.

In order to characterize the potential effect of inhibition of CA IX and XII in tumor hypoxia there is an implied need to develop small molecule, cell impermeable CA inhibitors for use in cell-based models of these extracellular, cancer-linked CAs in tumor hypoxia. Once characterized these molecules should have value as probes to further aid experimental advances in targeted cancer therapies associated with CA and tumor pH homeostasis. Our group’s research has focussed on small molecule medicinal chemistry of CA inhibitors, and we recently reported a library of S-glycosides that were potent inhibitors of CA isozymes IX and XII in vitro. Encouraged by the nanomolar activity of these compounds we now elaborate this novel compound class and evaluate for the first time carbohydrate-based CA inhibitors in cell-based models that emulate the role of CA IX in an acidic tumor microenvironment.

**Results and Discussion**

**Compound Design.** Sugar-based molecules have proven valuable drug leads, often presenting desirable activity and safety profiles. Many of the sugar-based drugs in clinical use are
antiviral, antibacterial or antifungal and benefit from improved solubility, tolerability, stability and/or targeting when compared to non-carbohydrate drugs. Work in our research group has demonstrated the versatility of the Cu(I) catalyzed 1,3-dipolar cycloaddition reaction (1,3-DCR or ‘click chemistry’) of organic azides and acetylenes to generate 1,2,3-triazole glycoconjugates. We have developed small molecule membrane impermeable carbohydrate-based CA inhibitors from alkynyl sugars and p-azidobenzene sulfonamide, as well as the ‘reverse polarity’ inhibitors from azido sugars and p-ethylbenzene sulfonamide. These compounds were designed to selectively target cancer relevant CA isozymes (with an extracellular active site) over other (intracellular) CA isozymes. Compounds comprise a hydrophilic sugar moiety tethered to an aromatic sulfonamide CA pharmacophore through an intervening triazole ring to provide a selection of membrane impermeable small molecule CA inhibitors.

The replacement of the naturally occurring O-glycoside bond by a S-glycoside bond is an approach practiced in the synthesis of carbohydrate containing compounds for downstream biological applications. This isosteric replacement seeks to enhance the stability of the small molecule glycoside towards enzymatic hydrolysis of the glycosidic bond whilst retaining vital molecular recognition interactions with the biological target. We have reported the synthesis and CA enzyme inhibition of S-linked glucose and galactose moieties tethered to a triazole- ArSO₂NH₂ motif, Figure 1a. Our intention here is to build structure-activity relationships (SAR) and structure-property relationships (SPR) around this compound class that can value add to the interpretation of CA inhibitor behaviour in cell-based assays. The target compounds of the present study were thus designed to incorporate a synthetic-handle that would allow further elaboration of the structure to 1,4,5-trisubstituted-1,2,3-triazoles. Specifically we chose
to incorporate an iodine atom at the 5 position of the triazole moiety of the target compounds, Figure 1b, this modification is key to further developing our molecular library.

\[ \text{S-glycoside} \]

\[ \text{1,4,5-trisubstituted triazole handle for synthetic elaboration} \]

**Figure 1.** a) S-glycoside 1,4-disubstituted-1,2,3-triazole CA inhibitor motif. b) S-glycoside 5-iodo-1,4-disubstituted-1,2,3-triazole CA inhibitor motif.

**Chemistry.**

Both Meldal\textsuperscript{22} and Sharpless\textsuperscript{23} discovered that catalytic Cu(I) leads to a dramatic rate enhancement (up to $10^7$-fold) of the 1,3-dipolar cycloaddition reaction (1,3-DCR) of organic azides (R-N$_3$) with alkynes (R′-C≡CH) with exclusive synthesis of the 1,4-disubstituted-1,2,3-triazole product. The reaction is now referred to as the copper-catalyzed azide-alkyne cycloaddition (CuAAC) and has rapidly become the foremost click chemistry reaction.\textsuperscript{24, 25} A recent variation to CuAAC involves the combination of a Cul/NBS catalytic system.\textsuperscript{26} This variation allows the *in situ* generation of $\Gamma^+$ and facilitates the formation of the 5-iodo-1,4-disubstituted 1,2,3-triazole product. We have applied this methodology to sugar alkyne and $p$-azidobenzene sulfonamide substrates, Scheme 1. In our hands this system generates two reaction products in similar yields, these are the 5-iodo- (Figure 1b) and the 5-H- triazoles (Figure 1a). We reconcile the formation of the two products to have resulted from competing reaction pathways, one in which the triazole-Cu intermediate is captured by $\Gamma^+$ (giving the 5-iodo- product) and the second where this intermediate is protonated (giving the 5-H- product).
This click chemistry variant thus gave useful quantities of two products both of which were valuable to the subsequent SAR and SPR investigations of CA inhibition.

We synthesized a set of triazole-based glycoconjugate sulfonamides 5-10 from p-azidobenzene sulfonamide 1 and peracetylated β-S-propynyl glycoside derivatives 2-4 in the presence of CuI and NBS, Scheme 1. Oxidation of the 5-iodo- (5, 7, 9) and 5-H- (6, 8, 10) 1,2,3-triazole benzenesulfonamide glycoconjugates to the corresponding sulfonyl derivatives 11-16 was achieved with an excess of m-CPBA. Deacetylation of the sugar moieties of glycoconjugate compounds was conducted using the standard Zemplén conditions27 of 0.05 M sodium methoxide in methanol, to afford compounds 17-26.

Scheme 1. Synthesis of target S-glycoside 5-iodo-1,4-disubstituted-1,2,3-triazole and glycoside 5-H-1,4-disubstituted-1,2,3-triazole CA inhibitor compounds.

Reagents and conditions. a) peracetylated β-S-propynyl glycoside (2-4, 1.0 equiv.), azide (1, 1.2 equiv.), CuI (1.2 equiv.), DIPEA (1.2 equiv.), NBS (1.2 equiv.), THF, rt, 16 h. b) m-CPBA (7.0 equiv), anhydrous CH₂Cl₂, 0 °C-rt, 2 h. c) NaOMe in MeOH (0.05 M, pH 12), anhydrous MeOH, 0 °C–rt, 30 min-16 h.
Chen et al. has recently demonstrated the application of the Sonogashira reaction to introduce an alkyne onto the 5-iodo-1,4-disubstituted triazole scaffold catalyzed by PdCl$_2$(PPh$_3$)$_2$ (10 mol%) and K$_2$CO$_3$ reporting both the ease and efficiency of the reaction (71 – 99%). Here we explored this chemistry with our iodo substrates, compounds 5 and 7, and the alkyne, propargyl alcohol. This short chain alkyne was chosen as it provides a hydroxyl functional group that is capable of picking up additional H-bonding interactions with the target CA protein with minimal additional steric bulk. A variety of Sonogashira reaction conditions were explored, many proceeded with either no conversion of the starting material, or starting material decomposition. The coupling reaction between the 5-iodo triazoles and alkyne was however achieved when using Pd(PPh$_3$)$_4$, CuI and Et$_3$N to give 1,4,5-trisubstituted triazoles 27 and 28, Scheme 2. This synthetic strategy has provided an additional layer of diversity within this class of CA inhibitor.

**Scheme 2.** Synthesis of target S-glycoside-1,4,5-trisubstituted-1,2,3-triazole CA inhibitors, compounds 27 and 28.

Reagents and conditions. CuI (1.0 equiv.), triethylamine (1.0 equiv.), propargyl alcohol (1.0 equiv.) in THF, nitrogen atmosphere, rt, 30 min; then Pd(PPh$_3$)$_4$ (1.0 equiv. in THF) is added, 50 °C, 30 min.

**Carbonic Anhydrase Inhibition.** The enzyme inhibition data for 5-28 as well as acetazolamide (AZA) were obtained for the physiologically dominant CA I and II, and tumor-associated CA IX and XII using a stopped flow assay that monitors the physiological reaction
CA catalyzed hydration of CO₂, Table 1.²⁹ AZA is a clinically used CA inhibitor. Similarly to AZA the S-glycosides 5-26 were potent inhibitors of hCA II, IX and XII, most within a range of narrowly distributed $K_i$ values (5.3-11.2 nM) with $K_i$ selectivity ratios close to unity, with only a few exceptions. The tight distribution of $K_i$ values on inhibitor activity for CA enzymes is consistent with our previously reported observations with this enzyme class.¹⁶a, ³⁰ This flat SAR showing minimal effect of compound structural variation on inhibition provides a valuable set of compounds as the presence of underlying consistent and high potency enzyme inhibition characteristics allows the relationship between physicochemical properties of the inhibitor and the performance in cell-based assays to be readily garnished. At hCA I inhibition by 5-26 was typically weaker (10-20 –fold) than for all other isozymes with $K_i$s in the high nM to low µM range and is also consistent with earlier studies with this compound class.¹⁶a The two trisubstituted compounds, 27 and 28 – both with a short hydroxyl bearing group at the 5 position on the triazole, demonstrated some noteworthy SAR regarding isozyme selectivity for the cancer-associated CAs. Compound 28 has much lower inhibition for both cytosolic CAs compared to all other compounds of this study, as a consequence it has much better selectivity for the cancer-associated CAs, particularly CA XII, where the $K_i$ is 9.0 nM and selectivity over CA II is 24-fold.

**Table 1.** Inhibition and isozyme selectivity ratio data of CA isozymes I, II, IX and XII with 5-28 and the established drug and CA inhibitor, acetazolamide (AZA).

Errors in the range of ± 5% of the reported value, from three determinations. The $K_i$ ratios are indicative of isozyme selectivity for cancer-associated CAs in vitro and are calculated as $K_i$ CA II/$K_i$ CA IX or XII.

**Cell-based screening of CA inhibitors.** To evaluate the impact of the CA inhibitors in cells we used our previously described in vitro systems of fibroblasts lacking endogenous expression of CA IX (CCL39-nhel’-pev, also named PS120-pev) and fibroblasts that overexpress the human form of CA IX (CCL39-nhel’-pca9, also named PS120-pca9). Exposure of both these cell types to nominally HCO$_3^-$-free media at two external pH$_o$ (7.5 or 6.4) can discriminate their viability. Exposure at pH$_o$ 7.5 does not affect cell viability, while exposure at pH$_o$ 6.4 sharply discriminates PS120 cells that are expressing or not CA IX. Indeed at this acidic external pH$_o$ 6.4 PS120-pev cells die while the PS120-pca9 remain viable. This differential survival under physiological pH versus acidic conditions is directly linked to the capacity of CA IX expressing cells to maintain a more alkaline pH$_i$ ensuring cell survival. PS120-pev cells (lacking CA IX expression) when grown in the neutral media system provide a control cell-based assay that allows us to evaluate the S-glycoside CA inhibitors for generic cytotoxicity. PS120-pca9 cells (overexpressing CA IX) when grown in the acidic media system provide a cell-based assay that allows us to evaluate the impact of S-glycoside CA inhibition on CA IX mediated cell viability. Together these two cell lines provide a cell-based model to study the likely effect of inhibition of CA IX in tumors with small molecules.

We focussed arbitrarily on the S-glucoside panel of compounds (5, 6, 11, 12, 17, 18, 21, 22) and the classical CA inhibitor drug AZA to study in the cell-based systems. The subset of eight S-glucoside compounds allow us to evaluate the full cross section of SAR and SPR. Compounds incorporate a spread of 5-iodo- (5, 11, 17, 21) versus 5-H- (6, 12, 18, 22) triazoles, acetylated (5, 6, 11, 12) versus deacetylated (17, 18, 21, 22) sugars and sulfur in two oxidation states: -S- (5, 6, 17, 18) and -SO$_2^-$ (11, 12, 21, 22). These compounds also encompass a range
of calculated Log P (cLog P) values, Table 2. cLog P represents intrinsic lipophilicity and compounds with Log P < 0 (such as 17, 18, 12, 21, and 22) typically have poor passive membrane permeability. All S-glucosides were potent CA II inhibitors ($K_i$ range 5.3-10.6 nM) with only compound 21 slightly weaker, yet still reasonably potent ($K_i = 49.2$ nM). Similarly all S-glucosides were potent CA XII inhibitors ($K_i$ range 5.3-10.7 nM) inhibitors, while 5, 6, 17, 12 and 22 were potent CA IX inhibitors ($K_i < 10$ nM), with 18, 11 and 21 less potent but still good CA IX inhibitors.

The effect of the S-glucoside CA inhibitors on cell viability on the two fibroblastic cell lines expressing or not CA IX is summarized in Table 2. Cells remained viable in the presence of the 5-H-triazole compounds (6, 18, 12, 22) at the highest concentration tested (300 µM) when grown at pHo 7.5. These compounds also had no impact on the CA IX-mediated cell viability at pHo 6.4, except for compound 6 which reduced cell viability only at 300 µM. Of the 5-iodo substituted compounds (5, 11, 17, 21), cells grown at pHo 7.5 remained viable in the presence of 17 at the highest concentration tested (300 µM), in the presence of 21 at 100 µM, in the presence of 5 at 60 µM, and in the presence of compound 11 at 30 µM. Compound 21 reduced cell viability of CA IX-expressing cells in acidic conditions (pHo 6.4) only at 300 µM, while compound 17 reduced viability of these cells at 100 µM. At a lower concentration (60 µM) only compound 5 was not able to sustain viability at the acidic environment (pHo 6.4). AZA reduced viability only at 300 µM, however there was also no cell type or pHo selectivity.

Table 2. Cell viability assays on CA IX-expressing cell model PS120-pca9 versus CA IX lacking cell model PS120-pev treated with S-glucoside compounds and AZA. The calculated Log P value is also included.

<sup>a</sup>cLog P data calculated using CS ChemDraw Ultra. <sup>b</sup>Viability in PS120-pev and PS120-pca<sub>9</sub> cells exposed to a pH<sub>o</sub> 7.5. <sup>c</sup>Viability in PS120-pca<sub>9</sub> cells exposed to a pH<sub>o</sub> 6.4. <sup>d</sup>+ indicates cells are viable; - indicates cells are not viable.

Among the eight S-glycoside inhibitors tested we identified two inhibitors (compounds 5 and 17) that demonstrated selective toxicity for PS120-pca<sub>9</sub> cells growing in a pH<sub>o</sub> 6.4 <em>in vitro</em>. 
The concentration of compound 17 needed to block CA IX-induced survival in the acidic media was however high (100 µM) and 17 was less suited to follow-up *in vitro* and *in vivo* studies than compound 5. Compound 5 blocked the CA IX-mediated survival in the acidic environment at 60 µM without general toxicity at pH0 7.5 in both cell lines (Table 2, Figure 2A). Compound 5 (60 µM for 30 min) reduced membrane-associated CA activity similarly to the level obtained in cells lacking CA IX (Figure 2B). Notably, 60 µM of AZA was not as effective as compound 5 at either abolishing CA IX-mediated cell survival in extracellular acidic conditions (Figure 2A) or in reducing CA IX activity (Figure 2B). In addition compound 5 (60 µM for 60 min) reduced the pHi of CA IX expressing PS120-pca9 cells exposed to a pH0 of 6.4 by 0.2 units. Under the same conditions, 60 µM of AZA had no impact (Figure 2C).

Figure 2: A. Cell viability assays for PS120-pev and PS120-pca9 cells in normoxia (21% O₂) as a function of the pH₀. Once attached cells were incubated in a HCO₃⁻-free media adjusted to pH₀ 6.4 or 7.5 for 24 h in a CO₂-free atmosphere in the absence (DMSO control) or presence of 60 µM of CA inhibitors AZA or compound 5. Fresh media containing HCO₃⁻ (40 mM) at pH₀ 7.5 was then added and the assay maintained for 4 days in a 5% CO₂ incubator before staining to visualize the cell density.

B. Rate of extracellular acidification in response to a CO₂-load on normoxic (21% O₂) PS120-pev and PS120-pca9 cells. The rate of acidification reflects the CA activity at the cell surface evaluated in the absence (DMSO) or in the presence of 60 µM of CA inhibitors (AZA or compound 5) 30 min prior CO₂-loading.
C. Compound 5 (60 µM) but not AZA (60µM), reduces the resting pH$_i$ of CA IX-expressing PS120-pca9 cells in an acidic HCO$_3^-$ -free media adjusted to pH$_o$ 6.4, but not pH$_o$ 7.5.

Next we investigated compound 5 in our human colon carcinoma cell model LS174Tr cells where we have previously demonstrated the *in vitro* and *in vivo* effects of knocking-down *ca9* and *ca12* genes via shRNA.$^4$ Control LS-shca9/ctl –Tet cells induced both CA IX and CA XII in hypoxia (Figure 2A). CA IX expression was reduced with a specific shRNA targeting *ca9* in control LS-shca9/ctl +Tet cells and in *ca12*-silenced LS-shca9/ca12$^-^+$Tet cells upon tetracycline (Tet) treatment. Following a 48-h treatment with 5 (60 µM) we observed reduced levels of mRNA (data not shown) and protein for CA IX in the control (*ca9*-nonsilenced) cell line LS-shca9/ctl –Tet in normoxia (N, 21% O$_2$) and hypoxia (H, 1% O$_2$) (Figure 3A). We also observed the concomitant upregulation of CA XII expression in these cells at the mRNA and protein level (Figure 3A). The effect of compound 5 on CA IX and CA XII expression mirrors exactly that obtained by us earlier with tet-inducible shRNA targeting *ca9* (LS-shca9/ctl +Tet) (Figure 3A). The lowest level of CA IX and CA XII ever observed in hypoxia was obtained in *ca9* and *ca12* double silenced cells (LS-shca9/ca12$^-^+$Tet) incubated with 60 µM of compound 5. Under the same conditions, 60 µM of AZA had no impact either on mRNA or protein levels of CA IX and CA XII (data not shown). Treatment of control colon LS-shca9/ctl –Tet cells with 5 (60 µM) in hypoxia (1% O$_2$) showed a 60% decrease in cell proliferation after 3 days and an additional 16% reduction on double-silenced LS-shca9/ca12$^-^+$Tet cells, consistent with the levels of CA IX and CA XII observed in these conditions (Figure 3B).
Figure 3: A. Impact of compound 5 (60 μM) treatment on CA IX and CA XII expression in colon carcinoma cells: control cells (LS-shca9/ctl –Tet) or Tet-inducible ca9-silenced cells (LS-shca9/ctl +Tet) or double ca9- and ca12-silenced cells (LS-shca9/ca12 +Tet). Stable LS-shca9/ctl and LS-shca9/ca12 cells were incubated with (+Tet) or without (-Tet) tetracycline for 4 days before incubation in either normoxia (N, 21% O2) or hypoxia (H, 1% O2) for 48 h in the
absence (-) or in the presence (+) of 60 µM of compound 5. Total cell extracts were analyzed by immunoblotting with antibodies against HIF-1α, CA IX, CA XII and Hsp90. The latter was used as a loading control.

B. Proliferation index of control LS-shca9/ctl –Tet cells or double silenced LS-shca9/ca12+Tet cells exposed to hypoxia (H, 1% O2) for 48 h in the absence (DMSO) or in the presence of 60 µM of CA inhibitors (AZA or compound 5). Total cell number was counted every 24 h during 3 days.

Our strategy to target the extracellular catalytic domain of cancer-associated CAs is to deliberately manipulate the physicochemical properties of the inhibitor to limit membrane permeability. Compound 5 has a clog P value > 0 (+1.98) and thus is predicted to have some cell membrane permeability, while the cLog P for 17 is < 0 (-0.16) and thus is predicted to be membrane impermeable. Despite their physicochemical difference these compounds were both identified as candidates that target CA IX in the cell models investigated. One explanation for the findings for compound 5 is that its high potency at CA IX (Ki = 6.2 nM) demonstrates that it is a strong binder to CA IX, and even though it is likely to be membrane permeable CA IX may act as an extracellular trap or ‘sink’ for compound 5 as a consequence of the high binding affinity. In the absence of CA IX over expression compound 5 is likely to enter cells through passive diffusion, however when CA IX is over expressed at the cell surface compound 5 may still bind and have the desired effect.

Conclusions

Both genetic silencing and immunotherapy targeting the modulation of CA IX and/or XII activity has been shown effective in vivo for therapeutically targeting hypoxic tumours. Small molecule CA IX and XII inhibitors thus represent a mechanistically novel opportunity with
potential for anticancer therapy intervention. From the perspective of targeted cancer therapeutics, this hypothesis so far remains to be comprehensively explored, and drug-like small molecule tools are needed to maximise the potential benefit of chemotherapies involving CA-mediated hypoxic tumor cell survival. We have designed and synthesized a new class of carbohydrate-based small molecule that very effectively inhibits both CA IX and XII enzymes. These inhibitors were studied in two fibroblast cell lines – one lacking endogenous expression of CA IX and one overexpressing CA IX. These in vitro systems allowed the discrimination of the protective role of CA IX in an acidic tumor microenvironment versus general cytotoxicity.

Our findings identified two inhibitors (compounds 5 and 17) that selectively blocked CA IX-induced survival. Extended studies with compound 5 showed that it reduced membrane-associated CA activity to a similar level as that obtained in cells lacking CA IX. Compound 5 was also investigated in our human colon carcinoma cell model (LS174Tr cells) where we have previously demonstrated the beneficial in vitro and in vivo effects of knocking-down either ca9 or ca12 or both ca9 and ca12 genes with shRNA. Compound 5 reduced levels of mRNA and protein for CA IX in control (ca9-nonsilenced) colon carcinoma cells in normoxia and hypoxia, while CA XII expression was upregulated. Notably, the effect of compound 5 mirrors exactly that obtained by us earlier with shRNA targeting ca9 gene expression. The lowest level of CA IX and CA XII ever observed in hypoxia was obtained in ca9 and ca12 double-silenced colon carcinoma cells incubated with compound 5. Consistent with the levels of CA IX and CA XII expression observed, colon carcinoma cells in hypoxia treated with 5 showed a 60% decrease in cell proliferation after 3 days and an additional 16% decrease in cell proliferation in ca9/ca12 double-silenced cells. Notably AZA, the clinically used CA inhibitor, was not as effective as compound 5 at either abolishing CA IX-mediated cell survival, reducing CA IX activity or reducing colon carcinoma cell proliferation. In summary, among the inhibitors tested herein two compounds were identified in this study that were able to
effectively discriminate cell viability in CA IX/XII cell-based models. We have shown that compound 5 is a candidate small molecule mimetic of the shRNA targeting ca9 that we have used in our previous studies. We conclude that small molecule CA inhibitors have potential for development as effective in vivo cancer-cell selective inhibitors.

Experimental Section

Chemistry - Materials and Methods

All starting materials and reagents, including per-\(O\)-acetylated sugars, were purchased from commercial suppliers. All reactions were monitored by TLC. TLC plates were visualized with UV light, sulfuric acid stain (5\% \(H_2SO_4\) in ethanol) and/or orcinol stain (1 g of orcinol monohydrate in a mixture of EtOH:\(H_2O:H_2SO_4\) 72.5:22.5:5). Silica gel flash chromatography was performed using silica gel 60 Å (230-400 mesh). \(^1\)H NMR spectra were acquired at 500 MHz and \(^{13}\)C NMR spectra at 125 MHz. Chemical shifts for \(^1\)H and \(^{13}\)C NMR spectra obtained in DMSO-\(d_6\) are reported in ppm relative to residual solvent proton (\(\delta = 2.50\) ppm) and carbon (\(\delta = 39.5\) ppm) signals, respectively. Chemical shifts for \(^1\)H NMR spectra obtained in CDCl\(_3\) are reported in ppm relative to residual solvent proton (\(\delta = 7.26\) ppm). Multiplicity is indicated as follows: s (singlet); d (doublet); t (triplet); m (multiplet); dd (doublet of doublet); ddd (doublet of doublet of doublet); br (broad). Coupling constants are reported in Hertz (Hz). Melting points are uncorrected. Mass spectra (low and high resolution) were recorded using electrospray as the ionization technique in positive ion negative ion modes as stated. All MS analysis samples were prepared as solutions in methanol. Optical rotations were measured at 25 °C and reported as an average of ten measurements. All compounds were analyzed for purity by HPLC with both UV (200 to 400 nm) and ELSD (Evaporative Light Scattering Detection) detection used. Purity of all compounds was ≥ 95%.
**General procedure 1. Synthesis of peracetylated β-S-propynyl glycosides.**

To a solution of the per-\(O\)-acetylated sugar (1.0 equiv.) in anhydrous CH\(_3\)CN at rt was added thiourea (1.5 equiv.) and boron trifluoride diethyletherate (1.5 equiv.). The resulting mixture was refluxed (~ 1 h), full consumption of the sugar starting material was evidenced by TLC (1:1 EtOAc/hexane). The reaction mixture was cooled to rt, triethyamine (1.5 equiv.) and propargyl bromide (1.5 equiv.) added and the reaction stirred at rt until completion (~ 4 h), evidenced by TLC (1:1 EtOAc/hexane). The solvent was evaporated and the resulting syrup diluted with CH\(_2\)Cl\(_2\), washed with HCl 5% (× 1) and brine (× 2), aqueous phases were back extracted with CH\(_2\)Cl\(_2\) (× 2). The organic extracts were combined, dried with MgSO\(_4\), filtered and the solvent removed *in vacuo*. The crude mixture was purified by flash chromatography as detailed to afford pure glycosides 2 – 4.

**General procedure 2. Dual synthesis of 5-iodo- and 5-H- 1,2,3-triazole benzenesulfonamide glycoconjugates.*26*

A solution of peracetylated β-S-propynyl glycoside (1.0 equiv.) and 4-azidobenzene sulfonamide (1, 1.2 equiv.) in THF was prepared. CuI (1.2 equiv.) and DIPEA (1.2 equiv.) were added, followed by dropwise addition of a solution of NBS (1.2 equiv.) in THF. The reaction was stirred at rt overnight. The solvent was removed *in vacuo* leaving a brown residue. This crude material was redissolved in CH\(_2\)Cl\(_2\), washed with 5% HCl (× 1) and brine (× 2), followed by back extraction of the aqueous extracts with CH\(_2\)Cl\(_2\) (× 2). The organic extracts were then combined, dried with MgSO\(_4\) and filtered. The solvent was removed *in vacuo* to produce a brown solid. Purification by flash chromatography, detailed below, afforded both the target 5-iodo substituted 5, 7, 9 and unsubstituted 6, 8, 10 1,2,3-triazole benzenesulfonamide glycoconjugates.
General procedure 3. Oxidation of 1,2,3-triazole benzenesulfonamide glycoconjugates.

A solution of the 1,2,3-triazole benzenesulfonamide glycoconjugate (1.0 equiv.) in anhydrous CH₂Cl₂ was prepared and cooled to 0 °C. A solution of mCPBA (7.0 equiv) in anhydrous CH₂Cl₂ was added dropwise and the reaction allowed to warm to rt. Oxidation of the starting material was complete after 2 h, with the reaction progress monitored by TLC. The reaction mixture was washed with NaHCO₃ (× 1) and brine (× 2), dried with MgSO₄, filtered and the solvent then removed in vacuo. The crude product was purified by flash chromatography, described below, to afford target compounds 11 – 16.

General procedure 4. Deprotection of glycoconjugates.

Fully deprotected sugars of glycoconjugates were prepared by treating the corresponding acetylated precursors (1.0 equiv.) in dry MeOH at 0 °C with methanolic sodium methoxide (0.05 M final concentration; pH 12). The reaction was warmed to rt and left to stir until full deacetylation was evident by TLC (CH₃CN:H₂O 9:1; 30 min - overnight). Neutralization of the solution by Amberlite IR-120-H⁺ ion-exchange resin, followed by filtration (the resin washed several times with methanol) and evaporation of the filtrate to dryness, afforded pure compounds 17 – 26.

General procedure 5. Synthesis of 5-substituted-1,2,3-triazole benzenesulfonamide glycoconjugates.

A solution of 5-iodo-1,2,3-triazole benzenesulfonamide glycoconjugate (1.0 equiv.) and Pd(PPh₃)₄ (1.0 equiv.) in THF was prepared and stirred at rt under an inert nitrogen atmosphere. A second solution, comprising CuI (1.0 equiv.), triethylamine (1.0 equiv.) and propargyl alcohol (1.0 equiv.) in THF, was stirred under an inert nitrogen atmosphere at rt.
After 30 min the two solutions were combined and the reaction stirred at 50 °C until complete consumption of the starting material was evidenced by TLC (~ 30 min). The reaction mixture was filtered through a pre-packed silica SPE cartridge and eluted with EtOAc. The solvent was removed from the crude product in vacuo, the residue redissolved in CH₂Cl₂ and washed with HCl 5% (× 1) and brine (× 2). The aqueous extracts were back extracted with CH₂Cl₂ (× 2). The organic extracts were combined, dried with MgSO₄, filtered and the solvent removed in vacuo. The crude product was purified by flash chromatography as described to afford the substituted triazole derivatives 27, 28.

**p-Azidobenzene sulfonamide (1)**

Sulfanilamide (10.0 g, 58.1 mmol, 1.0 equiv.) was dissolved in CH₃CN (300 mL) and the solution cooled to 0 °C. tert-Butyl nitrite (t-BuONO) (10.3 mL, 86.6 mmol, 1.5 equiv.) was added dropwise followed by dropwise addition of azidotrimethylsilane (TMSN₃) (11.5 mL, 86.6 mmol, 1.5 equiv.). The reaction mixture was stirred at rt and reaction progress monitored by TLC (1:1 EtOAc/hexane). After full conversion of the starting material the solvent was evaporated and the resulting syrup diluted with EtOAc (100 mL), washed with water (× 1) and brine (× 2). The aqueous extracts were combined and back extracted with EtOAc (× 2). The combined organic extracts were dried with MgSO₄, filtered and the solvent removed in vacuo to produce an orange solid. The solid was redissolved in EtOAc (150 mL) and reprecipitated with the slow addition of hexane (350 mL) to afford the title compound as a pale yellow solid (9.33 g, 47.1 mmol, 81% yield). ¹H NMR (500 MHz, CDCl₃): δ (ppm) = 7.93 (d, J = 8.5 Hz, 2H, H_{arom.}); 7.15 (d, J = 8.5 Hz, 2H, H_{arom.}); 4.84 (s, 2H, SONH₂), assignments were confirmed by ¹H-¹H gCOSY. LRMS (ESI⁺): m/z = 221 [M + Na]⁺.

**2,3,4,6-Tetra-O-acetyl-S-propynyl-1-thio-β-D-glucopyranoside (2)**
The title compound 2 was prepared from commercially purchased per-\(\text{O}\)-acetylated \(\beta\)-D-glucose according to general procedure 1 and isolated as a clear oil (76% yield) by flash chromatography (1:1 EtOAc/hexane). \(^1\)H NMR (500 MHz, CDCl\(_3\)): \(\delta\) (ppm) = 5.26 (t, \(J = 9.5\) Hz, 1H, H-3); 5.10 (t, \(J = 9.5\) Hz, 1H, H-4); 5.06 (t, \(J = 9.5\) Hz, 1H, H-2); 4.77 (d, \(J = 10.0\) Hz, 1H, H-1); 4.25 (dd, \(J = 12.0, 4.5\) Hz, H-6a); 4.15 (dd, \(J = 12.5, 2.0\) Hz, 1H, H-6b); 3.73 (ddd, \(J = 10.0, 4.5, 2.0\) Hz, 1H, H-5); 3.58 (dd, \(J = 16.5, 2.5\) Hz, 1H, SCHA); 3.29 (dd, \(J = 16.0, 2.5\) Hz, 1H, SChb); assignments were confirmed by \(^1\)H-\(^1\)H gCOSY. \(^13\)C NMR (125 Mz, CDCl\(_3\)): \(\delta\) (ppm) = 170.8, 170.4, 169.6, 169.5 (O\(\text{C}\)OCH\(_3\)); 82.3 (C-1); 78.9 (CH\(_2\)C\(\equiv\)CH); 76.2 (C-5); 74.0 (C-3); 72.1 (CH\(_2\)C\(\equiv\)CH); 70.0 (C-2); 68.5 (C-4); 62.2 (C-6); 20.9, 20.8, 20.7 (O\(\text{OCO}\)CH\(_3\)); 17.7 (CH\(_2\)C\(\equiv\)CH), assignments were confirmed by \(^1\)H-\(^13\)C HSQC. LRMS (ESI\(^+\)): \(m/z = 425\) [M + Na\(^+\)]. Analytical data is consistent with values reported in the literature.\(^{11}\)

**2,3,4,6-Tetra-\(\text{O}\)-acetyl-\(S\)-propynyl-1-thio-\(\beta\)-D-galactopyranoside (3)**

The title compound 3 was prepared from commercially purchased per-\(\text{O}\)-acetylated \(\beta\)-D-galactose according to general procedure 1 and isolated as a clear oil (82% yield) by flash chromatography (1:1 EtOAc/hexane). \(^1\)H NMR (500 MHz, CDCl\(_3\)): \(\delta\) (ppm) = 5.45 (d, \(J = 3.5\) Hz, 1H, H-4); 5.26 (t, \(J = 10.0\) Hz, 1H, H-2); 5.09 (dd, \(J = 10.0, 3.5\) Hz, 1H, H-3); 4.74 (d, \(J = 10.0\) Hz, 1H, H-1); 4.19-4.08 (m, 2H, H-6a, H-6b); 3.96 (m, 1H, H-5); 3.57 (dd, \(J = 16.5, 2.5\) Hz, 1H, SCHA); 3.31 (dd, \(J = 16.5, 2.5\) Hz, 1H, SChb); 2.26 (t, \(J = 2.5\) Hz, 1H, C\(\equiv\)CH); 2.16, 2.07, 2.05, 1.99 (4 \(\times\) s, 12H, O\(\text{OCO}\)CH\(_3\)), assignments were confirmed by \(^1\)H-\(^1\)H gCOSY. \(^13\)C NMR (125 Mz, CDCl\(_3\)): \(\delta\) (ppm) = 170.6, 170.4, 170.2, 169.9 (O\(\text{OCO}\)CH\(_3\)); 82.8 (C-1); 79.0 (CH\(_2\)C\(\equiv\)CH); 74.8 (C-5); 72.1 (C-3); 72.0 (CH\(_2\)C\(\equiv\)CH); 67.5 (C-4); 67.4 (C-2); 61.6 (C-6); 21.0, 20.9, 20.9, 20.8 (O\(\text{OCO}\)CH\(_3\)); 17.7 (CH\(_2\)C\(\equiv\)CH), assignments were confirmed by \(^1\)H-\(^13\)C
HSQC. LRMS (ESI\(^{+}\)): \( m/z = 425 \ [M + Na]^{+} \). Analytical data is consistent with values reported in the literature.\(^{11} \)

**2,2',3,3',4',6,6'-Hepta-O-acetyl-S-propynyl-1-thio-\( \beta \)-maltoside (4)**

The title compound 5 was prepared from 1,2,2',3,3',4',6,6'-hepta-O-acetyl-\( \beta \)-maltose according to general procedure 1 and isolated as a white solid (37% yield) by flash chromatography (1:1.2 EtOAc/hexane). \( R_{f} = 0.48 \) (1:1 EtOAc/hexane). \(^1\)H NMR (500 MHz, CDCl\(_3\)): \( \delta \) (ppm) = 5.35 (m, 1H, H-3); 5.27 (d, \( J = 4.0 \) Hz, 1H, H-1'); 5.21 (t, \( J = 10.0 \) Hz, 1H, H-3'); 4.98 (t, \( J = 9.5 \) Hz, 1H, H-4'); 4.97 (d, \( J = 9.5 \) Hz, 1H, H-1); 4.87 (dd, \( J = 10.5, 4.0 \) Hz, 1H, H-2'); 4.76 (t, \( J = 9.5 \) Hz, 1H, H-2); 4.39 (m, 1H, H-6a); 4.16 (m, 2H, H-6a', H-6b); 4.02 (m, 1H, H-6b'); 4.00 (m, 1H, H-5); 3.97 (m, 2H, H-5', H-4); 3.44 (br s, 2H, SCH\(_2\)); 3.18 (br s, 1H, C≡CH); 2.07, 2.02, 1.99, 1.99, 1.98, 1.95 (7 × s, 21H, OCOC\(_2\)H\(_3\)); assignments were confirmed by \(^1\)H-\(^1\)H gCOSY. LRMS (ESI\(^{+}\)): \( m/z = 708 \ [M + NH_4]^+, 713 \ [M + Na]^+ \).

**\( p\)-(4-{[2',3',4',6'-Tetra-O-acetyl-\( \beta \)-D-glucopyranosyl]thiomethyl}-5-iodo-1-H-1,1,2,3-triazol-1-yl)benzenesulfonamide (5) and**

**\( p\)-(4-{[2',3',4',6'-Tetra-O-acetyl-\( \beta \)-D-glucopyranosyl]thiomethyl}-1-H-1,1,2,3-triazol-1-yl)benzenesulfonamide (6)**

Title compounds 5 and 6 were prepared from azide 1 and alkyne 2 according to general procedure 2. Purification by flash chromatography (3:1 EtOAc/hexane) afforded compound 5 (43%) and 6 (45%) as light brown solids.

Compound 5: m.p. = 97-100 °C. \([\alpha]^{25}_D = -60 \ (c = 1.0, \text{ chloroform})\). \(^1\)H NMR (500 MHz, DMSO-\( d_6\)): \( \delta \) (ppm) = 8.06, 7.85 (2 × d, \( J = 8.5 \) Hz, 4H, H\(_{\text{arom}}\)); 7.58 (s, 2H, NH\(_2\)); 5.32 (t, \( J = 9.0 \) Hz, 1H, H-3'); 4.97 (t, \( J = 10.0 \) Hz, 1H, H-4'); 4.96 (d, \( J = 9.5 \) Hz, 1H, H-1'); 4.94 (t, \( J = 9.0 \) Hz, 1H, H-2'); 4.16 (dd, \( J = 12.5, 5.0 \) Hz, 1H, H-6a'); 4.07-4.00 (m, 4H, H-5, H-6b', SCH\(_2\));
2.01, 2.00, 1.99, 1.95 (4 × s, 12H, OCOCH₃), assignments were confirmed by ¹H-¹H gCOSY.

¹³C NMR (500 MHz; DMSO): δ (ppm) = 170.0, 169.5, 169.2, 169.0 (OCOCH₃); 148.4 (C arom.); 145.3 (C triazole); 139.0 (C arom.); 127.0, 127.0, 126.6, 126.6 (CH arom.); 85.2 (C triazole); 81.1 (C-1'); 74.4 (C-5'); 72.9 (C-3'); 69.6 (C-2' or C-4'); 68.1 (C-4' or C-2'); 61.9 (C-6'); 23.2 (SCH₂); 20.5, 20.4, 20.3, 20.2 (OCOCH₃), assignments were confirmed by ¹H-¹³C HSQC.

Compound 6: m.p. = 91-95 °C. \text{Carbonic anhydrase catalytic inhibition assay.} \text{ An SX.18MV-R Applied Photophysics stopped-flow instrument has been used for assaying the CA I, II, IX and XII } \text{CO}_2 \text{ hydration}
activity. Phenol red (at a concentration of 0.2 mM) has been used as indicator, working at the absorbance maximum of 557 nm, with 10 mM Hepes (pH 7.5) as buffer, 0.1 M NaClO₄ (for maintaining constant the ionic strength - this anion is not inhibitory), following the CA-catalyzed CO₂ hydration reaction for a period of 10 – 100 s. Saturated CO₂ solutions in water at 20 °C were used as substrate. Stock solutions of inhibitors were prepared at a concentration of 10 – 50 mM (in the assay buffer) and dilutions up to 1 nM done with the assay buffer mentioned above. Inhibitor and enzyme solutions were preincubated together for 15 min at room temperature prior to assay, in order to allow for the formation of the E-I complex. The inhibition constants were obtained by non-linear least-squares methods using PRISM 3. The curve-fitting algorithm allowed us to obtain the IC₅₀ values, working at the lowest concentration of substrate of 1.7 mM), from which Kᵢ values were calculated by using the Cheng-Prusoff equation. The catalytic activity (in the absence of inhibitors) of these enzymes was calculated from Lineweaver-Burk plots and represent the mean from at least three different determinations. Enzyme concentrations were 10.3 nM for CA I and CA II, 12 nM for CA IX and 15 nM for hCA XII. Enzymes used here were recombinant ones.

Cell Culture and Hypoxic Exposure.

Chinese hamster lung CCL39 fibroblasts (American Type Culture Collection) and the CCL39-derived mutant PS120 cells, lacking the amiloride-sensitive Na⁺/H⁺ exchanger, were maintained in DMEM (Sigma) supplemented with 7.5% FCS in a humidified atmosphere of 5% CO₂, 95% air, or 100% air at 37 °C. The colon adenocarcinoma cell lines LS174Tr, expressing the tetracycline (Tet) repressor were maintained in DMEM supplemented with 10% FCS and blasticidin (10 µg/ml, Invitrogen). The incubation in hypoxia at 1% O₂ was carried out at 37 °C in 95% humidity and 5% CO₂/94% N₂ in a sealed anaerobic workstation (Ruskinn).
Stable Transgenic Cells.

PS120 cells were transfected with the p\textit{ca}9 vector as previously described.\textsuperscript{4} LS174Tr cells were transfected with Tet (10 µg/ml)-inducible short hairpin RNA targeting \textit{ca}9 (sh\textit{ca}9) and transduced with lentiviral particles containing nontarget shRNA (\textit{ctl}) and shRNA-\textit{ca}12 (\textit{ca}12) to constitutively silence \textit{ca}12, as previously described.\textsuperscript{4} These cells are named, respectively, LS-sh\textit{ca}9/\textit{ctl} and LS-sh\textit{ca}9/\textit{ca}12 cells.

Immunoblotting.

Cells were lysed in a SDS sample buffer. Proteins (40 µg) were separated on 7.5% SDS polyacrylamide gels and transferred onto polyvinylidene difluoride membranes (Millipore). Membranes were blotted with the monoclonal M75 antibody to CA IX (Bayer), a polyclonal antibody to recombinant CA XII (Sigma), a polyclonal antibody HIF-1\textalpha prepared and validated in our laboratory and Hsp90 (Abcam). Immunoreactive bands were detected with a horseradish peroxidase (HRP) anti-mouse or anti-rabbit antibody (Promega) by enhanced chemiluminescence (Amersham Biosciences).

\textit{In cellulo} determination of CA activity.

Exponentially growing cells were scraped into ice-cold PBS to obtain intact cells expressing membrane-bound CAs. The cell suspension was centrifuged and resuspended in a HCO\textsubscript{3}-free media (Sigma) buffered at pH\textsubscript{o} of 7.5 with 30 mM HEPES in the presence or absence of the AZA or compound 5 at 60 µM for 30 min. A 0.1 volume of this cell suspension was added to a 3 mM HEPES-buffered solution (HBS) adjusted to pH\textsubscript{o} 8.2 before rapid addition to a CO\textsubscript{2}-saturated non-buffered solution and the extracellular pH determined over time (microelectrode,
Schott Instrument) to monitor the rapid hydration of CO₂ to carbonic acid in response to the membrane-associated CAs activity.

**Resting pHᵢ measurement [¹⁴C]-Benzoic Acid.**

The pHᵢ was measured using the technique of distribution of the weak acid [7-¹⁴C]-benzoic acid (Amersham Biosciences) in intracellular and extracellular spaces for exponentially growing cells.¹ 1h pre-incubation in the absence (DMSO) or in the presence of 60 µM of AZA or compound 5 was used before addition of the radioactive ligand.

**Cell-based screening of CA IX inhibitors.**

Fibroblasts expressing CA IX (PS120-pca9 cells) and control fibroblasts (PS120-pez cells) were seeded onto 12 well plates. Once attached, the medium was replaced by HCO₃⁻-free DMEM buffered at either pHₐ 6.4 (30 mM MES) or pHₐ 7.5 (30 mM HEPES), supplemented with 10% dialyzed serum, hypoxanthine 0.1 mM and uridine triphosphate 0.1 mM for 24h of growth in a CO₂/HCO₃⁻-free atmosphere without (DMSO) or with 60 µM of the CA inhibitors. Plates were then returned to 5% CO₂ in a regular media for 7 days before staining with Giemsa (Fluka).

**Proliferation assay.**

Tetracycline (1 µg/ml) was added in the medium of LS-shca9/ca12⁻ cells 4 days before the assay. LS-shca9/ctl –Tet and LS-shca9/ca12⁻ +Tet cells (6 x 10⁴) were seeded onto 6 well plates in the absence or presence of Tet. 24 h after seeding, cells were incubated in hypoxia (1 % O₂) in the presence or in the absence of CA inhibitors. Every 24 h during 3 days cells were detached and counted with Coulter Z1 (Beckman). The proliferation index was calculated by
dividing the total cell number obtained each day by the cell number obtained 24 h after seeding.
