Organizing Linked Data Quality Related Methods

Philippe A. MARTIN
ESIROI I.T., EA2525 LIM, Uni. of La Réunion, Sainte Clotilde, France
(+ adjunct researcher of the School of ICT, Griffith Uni., Australia)

Abstract - This article presents the top-level of an ontology categorizing and generalizing best practices and quality criteria or measures for Linked Data. It permits to compare these techniques and have a synthetic organized view of what can or should be done for knowledge sharing purposes. This ontology is part of a general knowledge base that can be accessed and complemented by any Web user. Thus, it can be seen as a cooperatively built library for the above cited elements. Since they permit to evaluate information objects and create better ones, these elements also permit knowledge-based tools and techniques – as well as knowledge providers – to be evaluated and categorized based on their input/output information objects. One top-level distinction permitting to organize this ontology is the one between content, medium and containers of descriptions. Various structural, ontological, syntactical and lexical distinctions are then used.

Keywords: Knowledge quality evaluation, Knowledge sharing ontology, Knowledge organization and best practices

1 Introduction

How should data or knowledge be represented and published so it can most easily be retrieved, re-used and managed? Then, how to compare or evaluate knowledge statements, knowledge bases (KBs), knowledge management techniques, KB management systems (KBMSs) and knowledge providers? Many complementary or alternative “knowledge sharing supporting elements” – and kinds of elements – have been proposed to provide partial answers to these research questions. For example: Semantic Web approaches [1-2], knowledge sharing languages (e.g., those provided by the W3C and more general ones [3-6]), ontologies [7-13], methodologies [14-15], best practices or design patterns [16-18], categories of evaluation criteria or measures [19-22], knowledge quality evaluation queries [23-25], benchmarks [26-27], techniques [28-29], software, etc. (these references are given to illustrate each “kind of element”; many of them will also later be referred to in this article; giving them now permits to group them by “kind” in the “references” section of this article).

However, it is difficult for a knowledge provider or a KBMS developer to know about all these elements or their sub-elements, to compare them, choose between them, combine them and have a synthetic organized view of what can or should be done for knowledge sharing purposes. Indeed, these elements often do not use similar terminologies or categorizations, and no ontology or library has been proposed to compare, index, organize and generalize these elements (which are at various levels of abstraction and may be contradictory). The top-level ontology presented in this article is a step in that direction. Thus, the goal of this article is to show how the problem cited at the beginning of this paragraph can be addressed. This article refers to this ontology or library as “this knowledge criteria/quality ontology” or simply “this (top-level) ontology”. It is currently focused on elements related to Linked Data [2].

As with any other ontology, the bigger and more organized it will become, the more useful it will be for the above cited knowledge sharing and retrieval tasks. (For the knowledge operationalization tasks, bigger is no longer better but eases the selection of knowledge for modules of relevant sizes and content for an application; this article and its top-level ontology only address knowledge sharing and retrieval tasks). This ontology is part of a KB published on-line via the WebKB knowledge server (usable at http://www.webkb.org). This KB – and hence the ontology presented in this article – can be cooperatively extended by any Web user via this server. To enable this, WebKB uses an abstract model and editing protocols [29] allowing its KB to be consistent and organized even though knowledge statements come from different sources and hence can contradict each other. Because of space restrictions this model is only quickly introduced in this article (it is not described) but this knowledge quality ontology exploits it and categorizes some of its features.

This ontology is only about information objects. Indeed, once information objects can be evaluated, knowledge management tools and techniques can be compared or evaluated with respect to (w.r.t) the qualities of the information objects that they allow as input and output, or lead their users to produce. Similarly, knowledge providers can be evaluated w.r.t. the information objects they have provided. Thus, unlike the “Semantic Web (SW) Topics Ontology” [10], this ontology does not attempt to semantically organize – i.e., does not attempt to use specialization relations, “part of” relations or other relations to organize – knowledge management tools, techniques or processes (e.g., tools and techniques for knowledge extraction, retrieval, matching, merging, representation, inferencing, validation, edition, annotation, modularization and publishing). This would be a huge task and, as for example illustrated by the “SW Topics Ontology”, these processes are so intertwined that they are difficult to distinguish and organize in a scalable way, i.e., in a systematic and non-arbitrary way within a specialization hierarchy and a part-of hierarchy. Here, “non-arbitrary” implies the use of conceptual distinctions – and especially, partitions – that are clear enough to lead different persons to categorize a same thing at a same place in a specialization/part-of hierarchy (note: a hierarchy does not have to be a tree). Such distinctions and hierarchies significantly reduce implicit redundancies [14].
The uppermost conceptual distinction used by this ontology to permit non-arbitrary categorizations of information objects is the clear partition of information objects into either description-content, description-medium or description-container objects. In this article, description-content objects are conceptual categories, as well as formal/informal terms or statements referring to or defining these categories. They are interpretations or abstractions of a (real or imaginary) situation or object. E.g.: abstract models, ontologies, terminologies, languages and any of their sub-elements (e.g., the concept/relation types of RDF and OWL). Description-medium objects are concrete model objects permitting to visually/orally/... present description-content objects. E.g.: graphical interface objects and syntax/style objects such as those specified by XML, CSS and XSLT. Description-container objects are the other information objects, i.e., non-physical objects permitting to store and manage description-content and description-medium objects. E.g.: files, file repositories, distributed databases and file servers.

The sections 2, 3 and 4 are respectively about the evaluation of description-content, description-medium and description-container objects. These sections relate, organize and generalize knowledge sharing best practices and quality criteria/measures from various sources. Some categories from each of the above referred articles are included in this quality ontology. [17-22] include the most complete lists of high-level categories that seemed to exist so far for Linked Data. All their categories are integrated in the quality ontology. The top-level of this ontology may be seen as validated by the fact it correctly organizes and generalizes all the quality-related categories that the author has found so far (this is a kind of “validation by usage”). On the other hand, this was obvious given the way this ontology was designed. The difficult part was to find this design. This ontology may also be seen as validated by the fact it follows the strongest best practices it categorizes (the ones that include or imply the weaker or more elementary best practices, e.g., the fact that a KB should at least be consistent). In [17-22], elements are only slightly categorized. This is shown by Section 5 which gives the four most organized quality related categorizations that seemed to exist for Linked Data so far. These categorizations are essentially only two levels deep and not always intuitive. Additional conceptual distinctions would be interesting, especially if they are “non-arbitrary” (under this condition, the more categories, the better).

2 Description content quality

This article cannot present the whole “quality ontology”. It can only show its top-level and its principles, i.e., the way this ontology manages to organize the main kinds of methodological elements, best practices, quality characteristics (e.g., evaluation criteria, quality dimensions, the “data quality indicators” of [22], ...) and quality measures (e.g., the “scoring functions” and “assessment metrics” of [22], ...) that have been proposed for knowledge sharing purposes. This article only shows important elements of a subtype hierarchy of quality measuring functions on information objects, with the function result being a value (typically, numerical or boolean). Indeed, all quality related categories and subtype hierarchies can be automatically derived from the above subtype hierarchy. E.g., relations can be derived from boolean functions (Figures 3 includes an example) and, from the above subtype hierarchy, it is possible to derive the one for quality characteristics and the one for “statements that have a certain (kind of) quality measure” (alias, “statements that follow a certain (kind of) best practice”).

There are many ways to categorize quality evaluations, e.g., according to the kind of objects they evaluate, and whether or not they take into account certain lexical, structural or semantic best practices. Figure 1 shows one intuitive uppermost categorization. In this article, indented lists show subtype hierarchies. In all such indented lists below, the XML namespace shortcut can be used but the prefix “pm:” is left implicit. “LDpattern:” is for [18], “LD:” for [20], “SF:” for [21] and “PD:” for [22-23]. C++/Java-like comments are used. Relation identifiers use nominal expressions and follow the common “graph reading convention”, i.e., the last argument is the destination of the relation. Thus, a binary relation R(X,Y) can be read “<X> has for <R> <Y>” (notes: <X> and <Y> may include quantifiers; furthermore, a relation “X has for subtype Y” may also be read “any instance of Y is also an instance of X”). For functional relations, the last argument is the function result.

Figure 2 gives subtypes to pm:description_content_quality. Two points explain those subtypes. First, one handy partition for description-content_semantic-quality functions is the distinction between those that give “correctness” values for the evaluated object and those checking that it includes certain things. Second, for each kind of evaluated source object, there are various ways to categorize i) functions that evaluate certain aspects of this kind of objects (e.g., the “correctness” and “conformity” aspects), ii) functions that evaluate “related” objects, and iii) functions that differently aggregate the values returned by these functions. In this article, within the names of the last two kinds of functions, “description” is abbreviated by “descr” in order to make the hierarchy more readable. The adjective “related” refers to actual or potential/allowed relations. E.g., RDF (a description content) allows various kinds of textual or graphical notations (description media) – some being standards, some not – even if most RDF-based tools (description containers) only work with RDF/XML. Some evaluation functions may for example better rate an RDF-based tool that can handle more notations (e.g., by calling external translation tools).

```
quality //function on an object with possibly other arguments;
//this function returns a value (numerical, boolean, ...)
content_based_quality //at least based on the object content
meta-statement_based_quality //ie., on meta-statements on the object
rating_based_quality //at least based on ratings
```

Figure 1. Important top types to organize quality measuring functions

```
description-content_quality //subtype of above function pm:quality

Figure 2. Important ways to evaluate description content quality
correctness  // of the evaluated object (statement or term  // referring to a statement)
LD: accuracy  // factual correctness of a statement (which  // should be a belief) w.r.t. the world
consistency  // reports all or some inconsistencies and  // implicit contradictions
consistency_of_this_statement_wrt_this_one (ST,ST -> boolean)  // this signature states that this function is boolean  // and has exactly 2 statements as arguments;
// one relation derivable from this function is:  // pm:statement_consistent_with_this_one (ST,ST)
consistency_and_non-redundancy_of_this_statement_wrt_this_one  // signatures are inherited when there is no ambiguity
consistency_of_this_KB (ST -> boolean)
consistency_of_the_RDF_KB  // the KB must be an RDF KB
consistency_of_SKOS_relations  // the measures of [24] are  // subtypes of this type
consistency_of_a_RDF_KB_tested_via_a_SPARQL_query  // as in [23] and [25]
LD: internal_consistency_fct  // SF: consistency_fct seems to  // be an alias of this type
LD: modeling_consistency_fct  // tests the correctness of the  // "logical structure of the data"; LD and SF do not  // precise if these last 2 types are dimensions or  // functions; this is why "_fct" is a suffix here;  // other relations and dimensions can be derived
substatements_of_this_1st_statement_that_are_inconsistent\_ // with_this_2nd_statement (ST,ST -> set)
consistency_ratio  // no restriction on the arguments but the  // result is a number (a ratio)
consistency_ratio_of_such_a_statement_in_this_statement  // one of the operators for defining term, here a function
(ST,ST -> number)  // such a statement: the 1st argument
consistency_ratio_of_all_substatements_in_this_statement  // the measures of [24] are  // subtypes of this type
(ST -> number)
consistency_ratio_of_relations_on_this_term_in_this_statement  // contextualized substatements
(ST -> number)
consistency_ratio_of_relations_on_this_term_in_this_statement  // number of non-conflicting frames
(term -> number)
PD: consistency  // divided by the “number of frames”

(pm%def_fct   ;; one of the operators for defining term, here a function
(pm%consistency_ratio_of_such_a_statement_in_this_statement
((?! ?s1 ?s2) ;; parameters; "?" is a KIF prefix for variable names;
;; as in all evaluation functions, the first argument
;; is the evaluated object; ?s2 may be a whole KB
(div (pm%cardinality ;; size of the set returned by “setofall”
(setofall ?s (and (pm%substatement ?s2 ?s) (=> ?s ?s1)  // (not (<= ?s2 (not ?s)))))
(pm%cardinality (pm%substatements ?s2))))

Figure 4. Full definition of one of the above functions, in KIF

[23] and [25] implement some quality measures (for whole RDF-based KBs) via SPARQL queries and SPIN rules. As noted in Figure 3, some of these measures are about consistency. They permit to check some aspects that KB building tools already verify or some complementary aspects. More classic and powerful consistency checking or other quality measurement cannot be done – or would be too complex and long to be done – via SPARQL queries. They require inference engines and definitions in expressive languages such as KIF [5]. The Common Logic ISO standard and its CLIF notation [6] are adaptations of the model and syntax of KIF but without features for specifying meta-statements, definitions and (monotonic or not) inference rules. This is why the data model (alias, meta-ontology) of WebKB is defined in KIF and why some definitions of its quality related ontology are in KIF. As illustrated by Figure 4, the functions referred to in this article are relatively easy to write in KIF. This figure shows the use of “pm%def_fct”, one of the primitive definition operators of the data model of WebKB, fully defined in KIF. These operators also permit to check and handle lexical/namespace and semantic contextualizations in a KB. “%” is used instead of “:” for XML-like namespace shortcuts because “%” and “#” have other meanings in KIF. “Semantic contextualization” refers to the embedding of a statement within a meta-statement for specifying information without which the statement may be false, e.g., information about the time, place and source of the content of the statement. Every statement must have at least one source (author, source document, etc.). This permits to consider “every assertion that is not a definition” as a belief. This is the main reason the KB can stay consistent while still allowing contradictory beliefs.

The KB editing/sharing protocols of WebKB also enforce the statement of relations – such a pm: corrective refinement – between contradictory beliefs. This avoids implicit partial/total redundancies and permits people or applications to choose between these contradictory beliefs when choices have to be made. Thus, no arbitrary selections has to be made a priori by the KB owners. E.g., a user may specify that “when browsing the KB or within the results of his knowledge extraction queries,” he wants to see only the most specialized corrections from certain kinds of sources. Furthermore, WebKB allows “default beliefs” and provides some default beliefs. E.g., a default belief for any user in WebKB is that, among contradictory statements, he believes the ones that correct the others without being contradictory between themselves. Since quality related measures can be specified as definitions or as beliefs, by creating or overriding some defaults beliefs, a user can easily specify which measures he believes in and wants to use, and how they should be combined. For more details on semantic/lexical contextualizations, default beliefs, and how to combine them, see the KIF formalization of the WebKB data model at http://www.webkb.org/kb/it/KSmodel.html
Conformity //reports on the existence/number of certain things or //patterns (thus, even SF:amount_of_data is a subtype of it)
Conformity_of_this_statement_wrt_this_requirement (ST,ST -> boolean)
Ratio_of_conformity_to_this_requirement_in_this_statement (ST,ST -> number)
Ratio_of_conformity_of_the_KB //no argument restriction here LD:modelling_granularity (-> number) //no argument PD:structuredness //e.g., PD:coverage (number of objects //with all relations of a schema) and //PD:coherence (average of coverage for all terms)
PD:completeness //alias, LD:completeness: (do all required //terms/relations exist?)

Quality_of_existing_or_derivable_contexts //temporal ones, //spatial ones, modal ones, …
Provenance //checks that the sources (agents/files) are //represented (LD:Attribution) and the creation dates //too (LD:History); LD:Authoritative is for checking //if the author is a credible authority in the domain
Loss_less_integration //checks that the semantics of //source objects was not changed; the data model of //WebKB and its protocols permits such an integration
PD:timeliness //alias SF:amount_of_data and LD:Currency; is //the object is up-to-date? E.g., PD:relevancy (timely //creation?) and PD:timeliness (timely update?)
SF:licensing //alias, LD:licensed; to check for an open //license, use PD:openness
Security //checks for signatures, encryption, //maintainability (LD:sustainable), …

Figure 5. Important subtypes of functions to evaluate conformity

Figure 6. Important functions to evaluate the quality of the representation of terms
3 Description medium quality

Description-medium quality functions evaluate the textual/graphic/... presentation that some (kinds of) description-medium objects permit for some (kinds of) description content objects in some (kinds of) description containers. The more the “presentation is distinguished from content” and the more structured (fine-grained) the content, the more the presentation can be finely adapted for different kinds of users and by the end-users. To that end, the W3C advocates the use of XML-based languages (e.g., RDF/XML) as well as CSS, XSLT and GRDDL. This last language indicates which XSLT scripts can be used to translate some knowledge published in some XML-based KRLs into other knowledge representation languages (KRLs). Fresnel [28] may be seen as a kind of advanced CSS for RDF-based KRLs.

Presentation evaluation functions may for example give high values to graphical/textual/audio/... interfaces composed of fine-grained objects with “rich contextual menus”. For each object, such menus would list i) presentation attributes/cmds for this object, and ii) semantic relations/cmds from/to/about this object to ease navigation, querying or updates. Although a syntax is clearly a presentation object, neither XML nor any current KRL seem to allow people to adapt their syntaxes, e.g., via the setting of some variables or the use of a notation ontology. Yet, this approach would be more flexible and easier to use than GRDDL, and hence can be used as one criteria by description-medium quality evaluating functions. Figure 7 gives a top-level specialization hierarchy for such functions. The general comments on the previous hierarchies also apply here: conventions, abbreviations, rationale for the specialization relations, etc.

```

Figure 7. Important functions to evaluate the quality of a description medium

4 Description container quality

Description-containers quality functions evaluate the way a given description container – e.g., a static file or a distributed KB server – i) modularizes, stores, makes retrievable and accessible (i.e., how it “publishes”) description content objects, and ii) checks or allows updates or queries on these objects. Compared to the independent and direct use of static files (e.g., RDF files), the use of knowledge servers eases knowledge modeling and reduces the implicit inconsistencies and redundancies between their knowledge statements. A KB server can also use static input/output files and offers much more flexibility than static files. It can also provide more services than those of a description-container (e.g., it can forward queries). This can be taken into account for evaluating its quality. Figure 8 gives a specialization hierarchy for description-container quality evaluating functions. The general comments on the previous hierarchies still apply.
“OPD:” is for [17] (this last source has three 3-level deep for [21], “Kahn” is for [19], “LDpattern:” is for [18] and even though they are essentially only two level deep. “SF:” is organized sources that so far seemed to exist for Linked Data, sources, Figure 9 lists show the structure of the four most ontology extends, generalizes and organizes the elements of its

Figure 8. Important ways to evaluate a description medium structural quality

5 Some other categorizations

In order to show how this knowledge criteria/quality ontology extends, generalizes and organizes the elements of its sources, Figure 9 lists show the structure of the four most organized sources that so far seemed to exist for Linked Data, even though they are essentially only two level deep. “SF:” is for [21], “Kahn” is for [19], “LDpattern:” is for [18] and “OPD:” is for [17] (this last source has three 3-level deep categories and one 4-level deep category). The first two sources are about quality criteria, the last two are about best practices. Their categories – the ones shown below – seem to be concept types. To permit a maximal integration of the various sources, they have been integrated into this quality ontology via function types, as illustrated by the previous indented lists. From these functions hierarchies, the concept types hierarchies can be generated. In the following lists of Figure 9, the lowermost categories are given within comments and without prefix for their source. The lowermost “OPD” subtypes have several instances in the OPD library.

Figure 9. Other categorizations for some elements in the quality ontology

| SF:Quality_criterion | //this categorization often (but not always) follows // the distinction between description content/medium/container SF:Content //Consistency, Timeliness, Verifiability SF:Representation //Uniformity, Versatility, Comprehensibility; //mixes criteria on descr. medium and descr. container SF:Usage //Validity of documents, Amount of Data, Licencing; //mixes criteria on descr. content and descr. container SF:System //Accessibility, Performance
| Kahn:Quality_dimension | //claimed to be “the 15 most important // ones from consumer perspective” Kahn:Intrinsic //Believability, Accuracy, Objectivity, Reputation Kahn:Contextual //Value-added, Relevancy, Timeliness, // Completeness, Appropriate-amount Kahn:Representational //Interpretability, Ease of understanding, // Consistency, Concision Kahn:Accessibility //Accessibility, Access security

| LDpattern:Publishing_pattern | //Annotation, Autodiscovery, //Document Type, Edit Trail, Embedded Metadata, //Equivalence Links, Link Base, Materialize Inferences, //Named Graphs, Primary Topic, Autodiscovery, //Progressive Enrichment, SeeAlso
6 Conclusions

This article has presented the top-level of an ontology organizing knowledge sharing best practices, design patterns, evaluation criteria and evaluation measures in a systematic, non-redundant and scalable way (e.g., by being based on distinctions on information objects rather than on processes). Some other research works on this subject mainly proposed lists of categories with, sometimes, some implementations (e.g., via SPARQL). The integration of these categories into this quality ontology shows that the results of these works cover only particular cases, which could sometimes be easily generalized. This ontology also permits to have a more synthetic view of the kinds of things that could or should be evaluated or done during knowledge sharing, or proposed by knowledge engineering tools. This ontology can be extended by Web users via the server which hosts it [29]. It could then be used as an index for elements of other libraries or ontologies. To that end, the bigger it will become, the more useful it will be. The presented ontology is, in some senses, validated by the fact it includes – or can be specialized to include – any quality related measures or criteria that the author has come across and by the fact it follows the strongest best practices it categorizes. Such an ontology is clearly application-independent. No particular use case would further validate it.

Section 2 also quickly introduced the data model of WebKB which enables i) loss integration of knowledge from various sources, and ii) the use of “default beliefs/rules/measures” to allow the combination of simple evaluation functions into complex ones and the re-use of other agents’ functions. The fact that knowledge on the Semantic Web is full of implicit contradictions and redundancies, very hard to evaluate, and often incorrect even with respect to the OWL primitives that it re-uses [27], may be an indication that KBMS developers and knowledge providers to the Semantic Web would benefit from such a data model and such an ontology of best practices and quality measures.
