ABSTRACT: Introduction: Many species of Syzygium are known to have antiseptic activity. Several Australian Syzygium species had roles as traditional bush medicines for Australian Aborigines although their antiseptic potential has not been rigorously studied. Methods: The antimicrobial activity of solvent extracts of Syzygium australe and Syzygium leuhmannii fruits were investigated by disc diffusion assay against a panel of bacteria and fungi and their MIC values were determined. Toxicity was determined using the Artemia franciscana nauplii bioassay. Results: The methanolic extracts of the fruit of both Syzygium species displayed the greater antibacterial activity of the extracts tested. S. australe generally had greater efficacy than the S. leuhmannii extracts. S. australe and S. leuhmannii fruit methanolic extract inhibited the growth of 13 (93%) and 12 (86%) of the 14 bacteria tested. Gram-positive and Gram-negative bacteria were both susceptible, although a slightly greater susceptibility of Gram-positive bacteria was noted. Nine (90%) and 8 (80%) of the 10 Gram-negative bacteria had their growth inhibited by S. australe and S. leuhmannii fruit methanolic extract extracts respectively. In contrast, methanolic extracts of both species inhibited growth of 100% of the Gram-positive bacteria tested. None of the extracts displayed broad antifungal activity. Indeed, none of the extracts inhibited the growth of A. niger or C. albicans. Only S. cerevisiae growth was affected and then only by the chloroform and hexane extracts. The methanolic, aqueous and ethyl acetate extracts of both Syzygium species were toxic in the Artemia franciscana bioassay, inducing significant mortality at <1000 µg/ml. Conclusions: The inhibitory bioactivity of S. australe against the bacterial panel validate Australian Aboriginal usage of S. australe leaves as antiseptic agents and confirms their medicinal potential, although care is needed in the uses of these extracts for these purposes due to their reported toxicity.

KEYWORDS: Syzygium australe, Syzygium leuhmannii, Australian plants, antibacterial activity, medicinal plants, toxicity

INTRODUCTION

Plants have long been used as medicines for treating a variety of different diseases and complaints. In many parts of the world plant preparations and medications continue to be used in the treatment of numerous disorders including eczema, malaria, respiratory disorders and infectious diseases.[1] Plant based medicines have a long history for the treatment of microbial infections in many traditional medicinal systems. For some of these plant treatments, antimicrobial activity has been proven. However, for many plant based antiseptics the evidence is anecdotal, or at best, epidemiological. Many traditionally used antiseptic agents have yet to be subjected to rigorous scientific investigation.

Syzygium is a large genus of evergreen flowering plants of the family Myrtaceae which consists of approximately 500 species.[2] Plants of this genus are widespread, occurring in tropical and subtropical regions of South-East Asia, Australia and Africa.[3] Many Syzygium species produce edible fruits and berries (eg. Syzygium jambos, commonly known as rose apple). In the commercially

most important species Syzygium aromaticum (clove), the unopened flower bud is used as a spice. This plant also has uses in traditional medicine due to its anaesthetic properties. The antibacterial activity of S. aromaticum is also well known. Numerous studies have reported on the antibacterial and antifungal activities of oils and extracts from this plant. Other Syzygium species from South East Asia (Syzygium jambos) and India (Syzygium lineare and Syzygium cumini) have also been shown to have antimicrobial activity. Much of our knowledge about the antimicrobial activities of Australian Syzygium species is anecdotal, although Australian Aborigines are known to have used some species as medicinal agents.

Recent studies within our laboratory have reported antibacterial activity in several Australia Syzygium several species. In particular, Syzygium australe (Bush Cherry) and Syzygium leuhmannii (Riberry) extracts have been highlighted as having particularly good antimicrobial potential. However, these previous studies have examined leaf extracts only, without reporting on the medicinal potential of the fruit. Recent studies have also demonstrated the exceptionally high antioxidant content of fruits of these plants. Antioxidants have been associated with the prevention of cancer, cardiovascular disease and neurological degenerative disorders. They are also linked with anti-diabetic bioactivities and have been associated with the reduction of obesity. Antioxidants can directly scavenge free radicals, protecting cells against oxidative stress related damage to proteins, lipids and nucleic acids. Therefore, T. lanceolata has potential in the treatment of a variety of diseases and disorders and its potential bioactivities warrant further investigation. The current study was undertaken to examine the antiseptic potential of S. australe and S. leuhmannii fruit extracts of against a panel of bacteria and fungi and examine their toxicity to determine their suitability for use as antibiotic medicinal agents.

**Materials and Methods**

**Plant material**

**Collection of plant samples**

S. australe and S. leuhmannii fruit were collected from verified trees in the suburbs of Brisbane, Australia and voucher specimens were deposited in the School of Biomolecular and Physical sciences, Griffith University, Australia.

**Preparation of crude extracts**

Samples were dried in a Sunbeam food dehydrator and the dried material was ground to a coarse powder. An amount of 1 g of each of the powdered samples was extracted extensively in 50 ml of either methanol, deionised water, ethyl acetate, chloroform or hexane respectively for 24 hours at 4°C with gentle shaking. All solvents were obtained from Ajax Australia and were of AR grade. The extracts were filtered through filter paper (Whatman No. 54) under vacuum followed by drying by rotary evaporation in an Eppendorf concentrator 5301. The resultant pellet was dissolved in 10 ml of deionised water. The extract was passed through 0.22 µm filter (Sarstedt) and stored at 4°C.

**Qualitative phytochemical studies**

Phytochemical analysis of the Syzygium extracts for the presence of saponins, phenolic compounds, flavonoids, polysteroids, triterpenoids, cardiac glycosides, anthraquinones, tannins and alkaloids was conducted by previously described assays.

**Antibacterial screening**

**Test microorganisms**

All media was supplied by Oxoid Ltd. Microbial strains were obtained from Tarita Morais, Griffith University. Stock cultures of Aeromonas hydrophilia, Alcaligenes faecalis, Bacillus cereus, Bacillus subtilis, Citrobacter freundii, Enterobacter aerogenes, Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Pseudomonas fluorescens, Salmonella salford, Serratia marcescens, Staphylococcus aureus, and Yersinia enterocolitica were subcultured and maintained in nutrient broth at 4°C. Aspergillus niger, Candida albicans, and Saccharomyces cerevisiae were maintained in Sabouraud media at 4°C.

**Evaluation of antimicrobial activity**

Antimicrobial activity of all plant extracts was determined using a modified disc diffusion assay. Briefly, 100 µl of the test bacteria were grown in 10 ml of fresh media until they reached a count of approximately 10⁸ cells/ml. 100 µl of microbial suspension was spread onto nutrient agar plates.

The Syzygium fruit extracts components were diluted to 10 mg/ml with deionised water and tested for antibacterial activity using 5 mm sterilised filter paper discs. Discs were impregnated with 10 µl (100 µg) of the test sample, allowed to dry and placed onto inoculated plates. The plates were allowed to stand at 4°C for 2 hours.
before incubation with the test microbial agents. Plates inoculated with *Alcaligenes fecalis*, *Aeromonas hydrophilia*, *Bacillus cereus*, *Citrobacter freundii*, *Klebsiella pneumoniae*, *Proteus mirabilis*, *Pseudomonas fluorescens*, *Serratia marcescens*, were incubated at 30°C for 24 hours, then the diameters of the inhibition zones were measured in millimetres. Plates inoculated with *Escherichia coli*, *Salmonella newport*, *Shigella sonnei*, *Staphylococcus aureus*, *Staphylococcus epidermidis* and *Streptococcus pyogenes* were incubated at 37°C for 24 hours, then the diameters of the inhibition zones were measured. All measurements were to the closest whole millimetre. Each antimicrobial assay was performed in at least triplicate. Mean values (± SEM) are reported in this study. Standard discs of ampicillin (2 µg) and chloramphenicol (10 µg) were obtained from Oxoid Ltd. and served as positive controls for antimicrobial activity. Filter discs impregnated with 10 µl of distilled water were used as a negative control.

**Minimum inhibitory concentration (MIC) determination**

The minimum inhibitory concentration (MIC) of the Syzygium extracts were determined as previously described.

Briefly, the plant extracts were diluted in deionised water and tested across a range of concentrations. Discs were impregnated with 10 µl of the test dilutions, allowed to dry and placed onto inoculated plates. The assay was performed as outlined above and graphs of the zone of inhibition versus concentration were plotted for each extract. Linear regression was used to calculate the MIC values.

**Toxicity screening**

**Reference toxins for toxicity screening**

Potassium dichromate (K₂Cr₂O₇) (AR grade, Chem-Supply, Australia) was prepared as a 1.6 mg/ml solution in distilled water and was serially diluted in artificial seawater for use in the *Artemia franciscana* nauplii bioassay.

**Artemia franciscana nauplii toxicity screening**

Toxicity was tested using a modified *Artemia franciscana* nauplii lethality assay. Briefly, 400 µl of seawater containing approximately 48 (mean 47.8, n = 125, SD 17.4) *A. franciscana* nauplii were added to wells of a 48 well plate and immediately used for bioassay. 400 µl of diluted plant extracts and the reference toxins were transferred to the wells and incubated at 25 ± 1°C under artificial light (1000 Lux). A negative control (400 µl seawater) was run in at least triplicate for each plate. All treatments were performed in at least triplicate. The wells were checked at regular intervals and the number of dead counted. The nauplii were considered dead if no movement of the appendages was observed within 10 seconds. After 72 h all nauplii were sacrificed and counted to determine the total% mortality per well. The LC₅₀ with 95% confidence limits for each treatment was calculated using probit analysis.

**RESULTS**

**Liquid extraction yields and qualitative phytochemical screening**

Extraction of 1 g of dried plant material from each species yielded dried plant extracts ranging from 62 mg to 442 mg (Table 1). The greatest amount of material (442 mg) was extracted from *S. leuhmannii* water extract. In general, the polar methanolic and aqueous solvents extracted the highest amounts of material, indicating the relatively high levels of polar compounds in the fruits of both species. Interestingly, the nonpolar chloroform extracts of both species also had high amounts of extracted material. The dried extracts were resuspended in 10 ml of deionised water, resulting in the extract concentrations shown in Table 1.

Phytochemical studies (Table 1) show that the methanolic and aqueous extracts prepared from fruits of both species contained high levels of water soluble phenolic phytochemicals. The ethyl acetate extracts of both species also contained moderate to high levels of water soluble extracts. Whilst the ethyl acetate extracts of fruits of both species also had detectable levels of water insoluble phenolics, these were detected only at low levels. The methanolic, aqueous and the ethyl acetate extracts of both species also showed low to moderate responses for flavonoids and saponins. Moderate levels of polysteroids and low to moderate levels of triterpenoids were also detected in the methanolic and aqueous extracts. Neither alkaloids nor anthraquinones were detected in any extract tested. Similarly, tannins were largely lacking, with only the *S. leuhmannii* methanol extract displaying any tannins, albeit only with a low response in this assay. Also noteworthy is the lack of detectable levels of any of the phytochemical classes tested for in the chloroform extracts of both species despite the large amounts of extracted material in these extracts. Chloroform would be expected to extract large amounts of lipids. The current study did not test for lipid levels so it is possible that much of this extracted material may consist of lipids, hydrocarbons and other nonpolar compounds.
Antibacterial activity

The Syzygium fruit extracts were tested for antimicrobial activity at the extracted concentrations (Table 1) in the disc diffusion assay against 14 bacterial and 3 fungal species (Figure 1). *S. australe* extracts were generally more effective antimicrobial agents than the *S. leuhmannii* extracts in terms of the diversity of the bacteria inhibited and the size of the zones of inhibition. In general, the polar methanol, water and ethyl acetate extracts had greater antimicrobial activity than the nonpolar chloroform and hexane extracts. Indeed, of the 14 bacterial species tested, the *S. australe* and *S. leuhmannii* methanolic extracts inhibited the growth of 13 (93%) and 12 (86%) bacterial species respectively. The water, ethyl acetate, chloroform and hexane extracts were less effective, with the *S. australe* water, ethyl acetate, chloroform and hexane extracts inhibiting the growth of 7 (50%), 9 (64%), 4 (29%) and 4 (29%) of the 14 bacteria tested respectively. The *S. leuhmannii* water, ethyl acetate, chloroform and hexane extracts had similar antibacterial profiles, inhibiting the growth of 5 (36%), 9 (64%), 4 (29%) and 3 (21%) of the 14 bacteria tested respectively.

Both Gram-positive and Gram-negative bacteria were affected by the methanolic fruit extracts although the Gram-positive bacteria appeared slightly more susceptible to the extracts of most of the Syzygium extracts tested (based on the number of species whose growth was inhibited). Of the 10 Gram-negative bacteria tested, the *S. australe* and *S. leuhmannii* methanolic extracts inhibited 9 bacteria (90%) and 8 (80%) respectively. In contrast, the *S. australe* and *S. leuhmannii* methanolic extracts both inhibited 4 of the 4 Gram-positive bacteria tested (100%).

The relative antibacterial activity strength of the extracts was evaluated by determining the MIC values for each extract against the bacteria which were shown to be susceptible by disc diffusion assays. MIC’s were evaluated in the current studies across a range of concentrations. This has previously been determined to be a valid method of MIC determination as MIC values determined by disc diffusion correlate well with those determined by broth dilution assays.[30] The antibacterial activity was generally strongest against Gram-positive bacteria with the MIC’s for several extracts against several bacterial species below 1 mg/ml (Table 2). The *S. leuhmannii* ethyl acetate extract in particular was a good inhibitor of the Gram-positive bacillus *B. cereus* (MIC 0.1 mg/ml) and the Gram-negative bacteria *S. sonnet* (MIC 0.7 mg/ml).
Table 2: Minimum inhibitory concentrations (mg/ml) of *S. austral* and *S. leuhmannii* fruit extracts against susceptible bacterial and fungal species

Numbers indicate the mean MIC values of at least triplicate determinations. – indicates no growth inhibition observed.

Figure 1. Antimicrobial activity measured as zones of inhibition (mm) of (a) *Syzygium austral* and (b) *S. leuhmannii*. Inhibition zones are represented as the means of at least triplicate experiments.
In contrast with their antibacterial activities, the *S. australe* and *S. leuhmannii* fruit extracts were poor inhibitors of fungal growth. Neither *A. niger* nor *C. albicans* growth were inhibited by any of the extracts tested. Only *S. cerevisae* growth was affected and only by the ethyl acetate and chloroform extracts of both species (Figure 1 and Table 2).

**Quantification of toxicity**

The Syzygium fruit extracts were diluted to 4000 µg/ml in artificial seawater for toxicity testing, resulting in a 2000 µg/ml concentration in the *Artemia franciscana* lethality bioassay. For comparison, the reference toxins potassium dichromate (800 µg/ml) was also tested in the *Artemia franciscana* lethality bioassay. For the reference toxins, the induction of mortality was seen within the first 4 hours of exposure. 100% mortality was evident following 8 hours of exposure (results not shown). In contrast, 12 hours was required for the Syzygium fruit extracts to induce the onset of mortality. By 24 h exposure, the methanolic, water and ethyl acetate extracts of both species had induced 100% brine shrimp mortality. The chloroform and hexane extracts were less toxic, inducing only low levels of mortality similar to that seen for the seawater control at 24 hours. The levels of mortality induction had increased by 48 hours for the *S. leuhmanni* chloroform and hexane extracts, with these levels approaching 100% mortality induction by 72 hours of exposure. In contrast, the *S. australe* chloroform and hexane extracts induced only relatively low mortality for the entire 72 hours exposure period.

To further quantify the effect of toxin concentration on the induction of mortality, the extract was serially diluted in artificial seawater to test across the concentration range 2000 µg/ml to 15 µg/ml in the *Artemia nauplii* bioassay at 24, 48 and 72 hours. Table 3 shows the LC$_{50}$ values of the Syzygium fruit extracts towards *A. franciscana*. No LC$_{50}$ values are reported for the *S. australe* chloroform and hexane fruit extracts at any time, nor for the *S. leuhmannii* hexane fruit extract at 24 h as less than 50% mortality was seen for all concentrations tested at these time points. Furthermore, the *S. leuhmannii* chloroform and hexane fruit extracts displayed low toxicity (generally > 1000 µg/ml) at all times tested and are therefore considered to be nontoxic. All other extracts tested displayed significant toxicity.

**DISCUSSION**

The current study reports on the antimicrobial activity and toxicity of fruit extracts of *S. australe* and *S. leuhmannii*. The ability of the leaf extracts to inhibit
the growth of both Gram-positive and Gram-negative bacteria is in agreement with previous reports of the antibacterial activity of other Syzygium spp.\cite{31-33} The greater susceptibility of Gram-positive bacteria seen in this study agrees with the previously reported specificities of South American, \cite{34} African \cite{35} and Australian\cite{36} plant extracts. Results within this laboratory have also confirmed the greater susceptibility of Gram-positive bacteria towards other Australian plant extracts.\cite{10,35} The Gram-negative bacterial cell wall outer membrane is thought to act as a barrier to many substances including antibiotics.\cite{35} The uptake of the Syzygium extract antibiotic agents by Gram-negative bacteria may be affected by the cell wall outer membrane of some bacteria. Individual Syzygium leaf components responsible for the antiseptic potential of the Syzygium leaf extracts were not identified in the current study. Further phytochemical studies are needed to purify and identify the antibacterial components from these extracts.

The findings reported here also indicate that the majority of the Syzygium extracts examined in this study displayed significant toxicity (<1000 µg/ml) in the Artemia nauplii bioassay. This toxicity would impact on the usefulness of these extracts as a medicinal antiseptic agent. Similar extracts prepared from fruits of these species have previously been reported to have high ascorbic acid levels.\cite{13} Whilst these ascorbic acid levels may have beneficial therapeutic effects, they may also be responsible (at least in part) for the toxicity reported here. Whilst A. franciscana have generally been reported to be a robust and hardy organism for toxicity screening, they are susceptible to pH changes.\cite{40} The levels of ascorbic acid previously reported in S. australe and S. leuhmannii extracts\cite{13} would be expected to have a significant impact on the pH of the seawater in the tests and this change may be responsible for the mortality induction reported in our study. Indeed, studies in our laboratory have shown that testing pure ascorbic acid in the concentrations previously reported to be in these extracts results in mortality similar to that reported in our study (unpublished results).

Whilst toxicity was assessed in this study with the test organism A. franciscana, toxicity towards A. franciscana has previously been shown to correlate well with toxicity towards human cells for many toxins.\cite{39} However, further studies are required to determine whether this is also true for the Syzygium extracts examined in these studies. Toxic antibacterial extracts may still be useful as non-medicinal antibacterial agents (eg. surface disinfectants and topical antiseptics). Likewise, toxic plant extracts may also still have medicinal potential even if they are not antimicrobial. Previous studies have demonstrated that toxicity in the A. franciscana bioassay may indicate anti-cancer potential.\cite{39} The toxic Syzygium fruit extracts should therefore also be tested against human cancer cell lines to determine their potential as anticancer drugs.

In conclusion, the results of this study indicate that the Syzygium leaf extracts examined in this report are worthy of further study due to their antibacterial activity. Conversely, the toxicity detected for these extracts indicates that further toxicity studies are required to evaluate the safety of these extracts for medicinal usage. Further evaluation of the antibacterial properties of these extracts against a more extensive panel of microbial agents is also warranted. Likewise, purification and identification of the bioactive components is needed to examine the mechanisms of action of these agents. Whilst the extracts examined in this report have potential as antimicrobial agents, caution is needed before these compounds can be applied to medicinal purposes. In particular, further toxicity studies using human cell lines are needed to determine the suitability of these extracts for these purposes.
