ABSTRACT

This study examines the relationship between senior managers' (SM's) transformational leadership style and department managers' (manager's) performance taking into account the impact of managers' gender on the relationship. A self-administered questionnaire was used to collect the data. Completed and usable questionnaires were received from 103 managers in charge of departments (accounting and finance, human resource management, sales and marketing, and customer services). The transformational leadership style (TLS) and performance were measured using instruments adapted from previous studies. The results revealed that superiors' TLS was positively associated with the performance of subordinate managers in charge of the above mentioned departments. The results also revealed that the managers' gender did not impact the relationship between the TLS and performance. Implications of the results are discussed later in the paper.

Keywords: leadership, relationship, senior managers, TLS

1. INTRODUCTION

Prior researchers have argued that superiors' (senior managers') TLS can motivate subordinates to improve their performance which, in turn, results in improved organisational performance (Patiar and Mia, 2009; Boerner et al., 2007; Hinkin and Tracey, 1994). The relevant literature (Boerner et al., 2007; Hinkin and Tracey, 1994) suggests that practising TLS is an effective management tool to deal with the increasingly competitive business environment. Managers with TLS can act as role models and inspire employees to put the good of the organization above self-interest (Patiar and Mia, 2009, Bass, 1985). Our literature search revealed that though a number of studies (e.g., Patiar and Mia, 2009; Boerner et al., 2007; Hinkin and Tracey, 1994; Boerner et al., 2007; Hinkin and Tracey) have investigated the relationship between TLS and performance in Western countries and developed economies. Proponents of contingency theory (e.g., Chenhall, 2003) suggest that the impact of factors such as TSL on an outcome variable depends on organizational context. This study investigated the relationship between TLS and managerial performance taking into account the potential impact of gender in the context of Bangladesh.

Gender mix in workforce is continually increasing around the world and senior managers need to understand the consequences of this trend (Leong & Seralica, 2001). Therefore, the question of whether a person's gender affects any aspect of his or her performance at work deserves inquiry. This study focused on finding if managers' gender affects the relationship between the TLS and performance.

2. THEORY AND HYPOTHESIS

2.1 The relationship between transformational leadership style and performance

Bass (1985) argues that superiors' having TLS are able to reveal a high level of trust in, communicate a sense of purpose to, and can inspire motivation among, subordinates by communicating important purpose in simple ways, promote intelligence, stimulation and problem solving behavior, and promote individuality. Previous researchers report that superiors with TLS are particularly able to motivate employees who, in turn, make better decisions and achieve improved performance. For instance, Xenikou and Simosi (2006) report that the TLS positively influences subordinates' performance by promoting subordinates' high level of motivation (see also Boerner et al., 2007, Wilkins et al., 2007) and Zelie et al. (1994) argue that motivated employees are more likely to deliver better performance. Patiar and Mia (2009) argue that a reason for the success of superiors with TLS in motivating employees to perform better is that they (superiors) empowers subordinates to make decisions without having first to seek the superior's approval.
In summary, previous research on the TLS indicates that superiors’ adoption of TLS creates a work environment conducive to sharing the organizational vision, inspiring and intellectually stimulating and instilling higher order ideals and values among subordinates (Bass and Avolio, 1997; Burns, 1978). The research also indicates that employees working under a superior with TLS are empowered and experience high job satisfaction and organizational commitment, which results improved performance (Arnold et al., 2001). Hypothesis one formally presents the discussions.

Hypothesis 1. There is a positive relationship between a superiors’ transformational leadership style and subordinates’ performance.

2.2. The impact of gender.

In today’s workplace, number of female employees is increasing in most countries around the world. So, management ought to understand the consequences of the increasing gender mix (Leong & Seralica, 2001).

However, though many studies conducted to assess the potential impact of employees’ gender on the relationship between a predictor variable and employee performance, the results are inconclusive. For instance, Campbell (2011) reports that, in some instances, a legitimate correlation between gender and an outcome variable such as performance or job satisfaction may be found within a specific workplace or organization under certain conditions and may not be found in other conditions.

This finding is consistent with other relevant research (Winant, 2006; Molnar, 2005); Gianakos, 2002; Ryan & Deci, 2000). Campbell (2011), concludes that overall within the United States, gender is not a reliable indicator or predictor of workers’ degree of satisfaction with a job.

Consistent with the findings of previous research on this issue, we also predict that there will be no difference in performance of female and male employees in an organization in a developing economy like that in Bangladesh. Hypothesis 2 formally presents this argument.

Hypothesis 2. Employees’ gender has no impact on their performance.

3. RESEARCH METHOD

3.1. The Sample. The data were collected from department managers in charge of accounting and finance (AF), personnel/human resource management (HRM), sales and marketing (SM), and customer service (CS) departments in 103 medium to large (annual sales revenue of BDT. 900 millions to 1200 millions) financial services, garments, and nongovernment organizations in Bangladesh.

3.2. The Data Collection.

Initially, the GMs (general manager, HRM) of 150 medium to large organisations were contacted in writing explaining the purpose of the study and assuring complete confidentiality of the information to be collected.

Each GM was assured of (i) using the information only for the study, (ii) providing the overall aggregate results of the study, and if desired (iii) explaining the results in a seminar for management of the participating companies. A sample of the questions used for the data collection was provided and explained to the GMs.

Out of the 150 GMs contacted, 58 agreed to let her/his company participate in the study and provided contact of 232 department managers. We wrote a personal letter to each of the 232 managers (a) explaining the purpose of the study, (b) assured anonymity of all participants and, attached with a copy of the finalised questionnaire and a prepaid self-addressed envelope for returning the completed questionnaire direct to the author. Out of the 232 nominated department managers, 103 (53 male and 50 female) fully completed and returned the questionnaire.

Thus, the final sample was 103 yielding a response rate of over 44.4%. On average the participants
had worked for their firms for 6 years ranging from 4 to 11 years, were 25% in charge of AF, 27% in charge of HRM, 26% in charge of SM and 22% in charge of CS departments
3.3. Measurement of Variables
3.3.1. Transformational leadership style
To measure TSL, this study followed Patiar (2005) in using Bass and Avolio's (1997) revised Multifactor Leadership Questionnaire (MLQ-Form 5X) comprising 20 items related to superiors TLS. Ali 20 transformational leadership items were measured using a 5-point Likert scale where managers were asked to indicate how often the 20 TLS behaviors represent their general manager.

Here, 1 indicated "almost never" and 5 indicated "almost always". Consistent with the approach of Avolio et al. (1999), Banerji and J-rishnan (2000), Chen (2004), the mean of 20 items was taken to compute the global score representing the managers' perceptions of their GM's TLS.

The Cronbach alpha 0.89 for the overall sample achieved was in line with that between .87 and .96 reported by other researchers (e.g., Arnold et al., 2001) and was satisfactory as it is above 0.70, recommended by Nunnally (1978). The descriptive statistics for TSL, [(for the overall sample was 3.77 with 0.68 (std. dev.) and 1.00-500 (min- max actual range)), (for the Female was 3.35 with 1.08 (std. dev.) and 1.00 – 500 (min – max actual range)] and for the Male managers was 3.33 with 0.96 (std. dev.) and 1.00-500 (min- max actual range)] respectively.

3.3.2. Managerial performance
Since the present study was concerned with managerial performance, we followed Ferris (1977) in defining the construct as the extent of managers' achievement of target (planned) performance. Ferris's definition of performance is especially suitable for defining managerial performance where jobs are complex and less predictable/routine (see Mia, 1984).

The managers were asked to indicate using a 5-point Likert scale the extent to which they achieved their overall planned performance during last year. On the scale, 1 indicated "very low" and 5 indicated "very high".

The descriptive statistics for performance [(for the overall sample was 3.21 with 0.97 (std. dev.) and 1.00-500 (min- max actual range)), (for the Female was 3.23 with 0.78 (std. dev.) and 1.00-500 (min- max actual range)] and for the Male managers was 3.19 with 0.81 (std. dev.) and 1.00-500 (min- max actual range)] respectively.

3.3.3. Gender was measured as 1 =Female; 0 =Male.

4. RESULTS
4.1. Test of the Hypothesis
Hypothesis H₁ predicts a positive relationship between department managers' performance and the general managers' TSL.

It was tested by regressing performance against TSL. The model explained 6.9% of the variance (R. Square= 6.90%; Adjusted R Square = 4.50%; F(l,1021 = 5.91; P=0.05) in managerial performance.

Also, the results revealed that the relationship between TSL and managers' performance was positive and significant (the regression coefficient (β) = 0.186, T value = 1.921, p < 0.05), therefore the hypothesis was supported.

Hypothesis H₂ predicts that managers' gender has no impact on the TSL-performance relationship. It was tested by sub-dividing the overall sample into Female and Male managers and then performance for each group was separately regressed against TSL for the group.

The results for both of the groups were nonsignificant, therefore supporting the hypotheses that managers' gender does not influence the TSL-performance relationship.

5. DISCUSSION, LIMITATION AND CONCLUSIONS
As hypothesis H₁ was supported, the fundamental argument in the study that superiors is a powerful factor that can influence employee performance. We argue that superiors' TLS is an effective management tool for motivating managers to try their best to improve their performance which, in turn,
may improve organizational performance. The study also confirms that employee gender is not a reliable factor for predicting performance in a developing economy. This study confirms the results reported in prior studies (see Campbell, 2011).

The following limitations to this study deserve to be mentioned here. First, since the GMs of the initially selected organisations nominated the department managers to participate in the study, there could be a systematic bias in the sample.

Although we did not find any significant difference between the participating and the non-participating firms in terms of size, it is possible that managers in high performing firms completed our questionnaire.

Therefore, a generalization of the results requires caution. Second, the sample is based on department managers of the medium to large firms operating only in Bangladesh. Therefore, caution is needed in generalizing the findings to firms in other countries and to other managers. Future research to generalize the results: (i) to the next level of managers and (ii) to firms operating in other countries will be useful.

A practical implication of the results is that the top management in firms may consider encouraging senior managers to adopt TLS in dealing with their subordinate managers. This attempt may be supplemented by arranging suitable training for the senior managers to practice TLS.

A theoretical implication of the results is that the study confirms the usefulness of TLS as an important factor in improving employee performance even in a developing economy.
