## Self-report prospective memory problems in people with stroke

### Abstract

**Background and Purpose:** Prospective memory (PM) is a common problem which can limit performance of basic and instrumental activities of daily living in stroke patients. We compared self-report PM failures between older and younger people with stroke, examined differences in perceptions of PM failures between people with stroke and relatives, relationships between these PM failures and functional performance.

**Methods:** A total of 105 stroke patients, 65 relatives and 112 healthy controls were recruited. Both the stroke patients and controls were further divided into an older (age >55 years) and a younger (age ≤ 55 years) group. Data for stroke patients and relatives were obtained via the Brief Assessment of Prospective Memory (BAPM), **Basic Activity of Daily Living (BADL) related Modified Barthel Index (MBI)** and **Lawton Instrumental Activities of Daily Living (Lawton IADL) Scale**. Healthy controls' data were also collected.

**Results:** The older stroke group had significantly higher BAPM total scores and BADL and IADL subscale scores than the younger group. Difference in perceptions of the patients' self-report of PM failures and their relatives' report was significant for the IADL subscale. Self-report of PM failure was significantly related to functional BADL and IADL measures.

**Conclusions:** Results highlight the impact of PM failures in stroke patients and their assessment, management, and rehabilitation of these patients.

**Key Words:** prospective memory, stroke, functional, age, ADL, IADL

## Introduction

According to a recent World Health Organization Global burden report [1], stroke was one of the main causes of death and disability in the world. 15 million people worldwide suffer a stroke 2014. Of these, 5 million died and another 5 millions are left permanently disabled, placing a burden in family and community. Incidence of stroke has been associated with older age and about 75% of stroke occurs over the age of 65 years [2, 3]. Nowadays, significant numbers of people suffer strokes at a younger age [4, 5]. About 12 % of stroke patients report their first stroke between 18 and 50 years [6]. The incidence of stroke in young people in both North America and Western European countries in the 1980s was about 4% [7, 8]. More recently 25 % of stroke patients in the UK were young people [9] and it was estimated that 2 million young people suffer a stroke every year in the world [10]. However, the definition of young stroke can be different from one study to another. Some studies considered persons with stroke who were aged between 18 and 65 years as younger stroke survivors [9, 11]. Other studies defined younger stroke patients as patients up to 45 years or 55 years of age [12]. In the present study, the age range of ‘younger stroke’ patients was operationally defined as between 18 to 55 years old and those over 55 years were considered older stroke patients, as there is an increase in life expectancy and more and more people are retiring late.

As a medical emergency, stroke can cause permanent neurological damage, complications, adult disability, and death [13]. Permanent neurological damage may affect many aspects of functioning including attention, memory, reasoning, perception, vision and motor control [14]. Memory deficits, including prospective memory (PM) impairment [15], can be one of the most obstructive factors that influence the two types of daily living activities: performance of basic (BADL) and instrumental activities of daily living (IADL) [16]. BADL refers to basic daily routine including self-care activities such as bathing, dressing, feeding and using the toilet. IADL

1  
2  
3 refers to more complex task such as using the telephone, preparing meals, shopping and using  
4  
5 public transport. PM refers to the ability to “remember to perform an intended action at a  
6  
7 particular point in the future” [17]. It can be divided into three sub-types, namely, time-based,  
8  
9 event-based and activity-based [18]. All three types of PM require the execution of an intended  
10  
11 action in a delayed situation while performing an on-going task at the same time. For time-based  
12  
13 PM, the intended action should be performed at a specific time, such as an appointment at 10 a.m.  
14  
15 For event-based PM, the intended action should be performed when a particular cue appears (e.g.,  
16  
17 call the manager when an invited customer arrives at the office). Finally, activity-based PM is  
18  
19 similar to event-based PM in that both require a person to carry out an intended action when a cue  
20  
21 appears. However, the former it does not involve the interruption of the on-going task. An  
22  
23 everyday example of activity-based PM task is switching off the computer when one finishes  
24  
25 checking all the e-mails. Most PM researchers contrast PM with retrospective memory (RM).  
26  
27 According to Cockburn [19], RM and PM are similar in that memory for content is essential to  
28  
29 both. However the essential differences between these two memory constructs are: (1)  
30  
31 remembering prospectively also requires memory for intention, and (2) the cue for retrieval has to  
32  
33 be self-initiated in PM but not in RM. Similarly, Einstein and McDaniel [20] suggested that while  
34  
35 someone (e.g., an experimenter or a teacher) initiates or requests the act of remember in RM, PM  
36  
37 requires a person to remember to remember in the first place. PM has a major impact on  
38  
39 individuals’ quality of life as well as ADL. Impairment of PM can make rehabilitation more  
40  
41 difficult. Patients might not be able to follow through steps towards any organized meaningful  
42  
43 activity or remember to initiate strategies or practice activities outside of therapy sessions.  
44  
45 Assessment and intervention of a patient’s PM impairment should therefore be an important focus  
46  
47 of any cognitive rehabilitation program.

Research in the schizophrenia area has shown that better performance on PM tests predicts higher functional capacity as measured by a standardized **activity of daily living** (ADL) scale [21]. Given the significant effects a stroke can have on the brain, it is logical to assume that stroke patients would have PM problems [22-24]. In addition, given the effect of ageing on both RM and PM, younger and older stroke patients are expected to show different levels of PM impairment [25]. To date, however, few studies have compared the performance between young and old stroke patients as well as with healthy control groups to investigate whether they showed significant differences on different types of PM tasks. Thus, the aims of the current study were to explore whether there was a difference in frequency of PM failure between two stroke patient groups (younger and older) and their corresponding age-similar healthy control groups in their self-report PM, and to explore the differences between stroke patients' self-report of PM failure and their relatives' reports. Finally, we aimed to examine the relationships between PM failure and functional BADL and IADL performance in the two stroke groups as a whole.

## Method

### Study design and participants

This study used a cross-sectional survey design and a mailed questionnaire to examine stroke patients' self-report PM failures and their functional abilities. Similar questionnaires were sent to their relatives or main caregivers to fill in. The stroke and family participants were recruited from local hospitals, rehabilitation centers, day hospitals, outpatient clinics and self-help groups in Hong Kong. While the younger healthy controls were recruited from The Hong Kong Polytechnic University, the older controls were recruited through three local elderly services centers run by a large NGO called The Neighbourhood Advice-Action Council (NAAC). The convenience

1  
2  
3 sampling method was used in this study for selecting both stroke patients and health control. The  
4  
5 inclusion criteria for stroke patients were: (a) age 18 years or above; (b) either gender; (c) a  
6  
7 diagnosis of suffering from a stroke as confirmed by a CT or MRI scan and had a post stroke  
8  
9 period over 6 months; (d) willingness to participate. The exclusion criteria were: (a) being  
10  
11 diagnosed with other neurological conditions such as Parkinson's disease, traumatic brain injury,  
12  
13 epilepsy etc.; (b) having a recurrent stroke; (c) alcoholism; (e) associated psychiatric and  
14  
15 behavioural symptoms; (f) dementia or mild cognitive impairment (MCI)  
16  
17  
18  
19  
20  
21

## 22 **Instrumentation**

23  
24 A similar 4-part questionnaire was put together for both stroke patients and their relatives. The  
25  
26 first part covered personal demographics including age, gender, marital status, educational level  
27  
28 and types of hemiplegia. For relatives, the relationship with the patients was also recorded.  
29  
30  
31

32 The second part was a validated Brief Assessment of Prospective Memory (BAPM) [26].  
33  
34 This self-report instrument consists of 16 questions which are related to PM in both basic  
35  
36 activities of daily living (8-item BAPM-BADL) and instrumental activities of daily living (8-item  
37  
38 BAPM-IADL). Previously it has been used for evaluation of PM performance in people with  
39  
40 traumatic brain injury. Frequency of PM failure in the last month is self-rated on a five-point scale  
41  
42 where 1 = 'never' and 5 = 'very often'. Items can also be scored as 'not-applicable'. Mean scores  
43  
44 for the BADL and IADL subscales and total scores are calculated by adding item responses  
45  
46 together and then dividing by the total number of items rated, with not applicable responses  
47  
48 excluded from the mean scores. Subscale scores can therefore range from 1 to 5 with higher  
49  
50 scores indicating more frequent PM failure.

The last two parts of the questionnaire aimed to assess the functional level of patients and included the Modified Barthel Index or MBI [27] for evaluating the patients' BADL and the Hong Kong Lawton IADL Scale [28, 29] for assessing IADL. The former is a 10-item index which is targeted at measuring the degree of independence of a patient, covering areas such as feeding, transfer, grooming and toilet use and has a score range of 0-20 [30]. The latter scale, developed by Lawton, defines IADL as complex activities vital to maintaining independent living in the community. In the present study, the Hong Kong version was used and it consists of a total of nine items (including the use of telephone, transportation, shopping, medication management, money management, meal preparation, housework, and laundry work) with scores ranging from 0-27. For healthy controls, a shorter questionnaire consisting of basic personal information and was used, instead of the full version used with the stroke patients and their relatives.

### Procedures

Ethical clearance was obtained from the Research Ethics Committee of participating centers, hospitals under Hospital Authority and The Departmental Research Committee of Rehabilitation Sciences, The Hong Kong Polytechnic University respectively. Patients with stroke who met the selection criteria were invited to participate in the study. Firstly, the researchers sent the consent forms and questionnaires to the recruiting centers and hospitals. Secondly, written consent from participant was obtained by therapists or center staff, and returned within one week. The questionnaires together with return-mail envelopes were then sent to consenting participants by mail and they were asked to return the completed package within 2 weeks. A reminder was sent after the deadline of reply. Students recruited as younger healthy controls from the Hong Kong Polytechnic University were invited to complete the questionnaire on campus. The elderly

1  
2  
3 participants were recruited through the NAAC and they were assisted to fill in the questionnaire  
4  
5  
6 by center staff.  
7  
8  
9

### 10 **Statistical Analysis**

11  
12 Data were analyzed using IBM SPSS Statistics for Windows (Version 20.0) [31]. Descriptive  
13  
14 statistics were obtained for basic demographic data such age, gender, education level, types of  
15  
16 hemiplegia, post stroke period, history of illness. Independent samples t-tests or Chi-square tests  
17  
18 were used to test for homogeneity of the stroke and corresponding age-similar groups in their  
19  
20 demographics such as age and gender. Comparisons of BAPM scores (BADL, IADL, TOTAL)  
21  
22 between stroke groups (the younger and older stroke groups); between stroke and the age-similar  
23  
24 healthy control groups, and between stroke patients and their relatives who also responded to  
25  
26 questionnaire study. The analyses were conducted using one-way Analysis of Variance and post-  
27  
28 hoc test using Tukey's test. Associations between BAPM scores and functional BADL and IADL  
29  
30 were examined using Pearson's correlation coefficients.  
31

### 39 **Results**

#### 40 **Demographic data**

41  
42 Table 1 shows the demographics of the stroke and healthy control groups. A total of 217  
43  
44 participants were successfully recruited. There were 105 stroke patients and 65 (62%) of their  
45  
46 relatives also agreed to take part in the study. Their relationships with patients were respectively  
47  
48 spouses (75.4%), children (13.8%), parents (4.6%), siblings (4.6%) and others (1.5%). Of the  
49  
50 stroke group, 29 and 46 were classified according to their age range as the younger and older  
51  
52 stroke group respectively. For the 112 healthy controls, there were 46 younger and 66 older adults  
53  
54  
55  
56  
57  
58

60

1  
2  
3 respectively. There were no statistically significant differences in age, gender and educational  
4 level respectively between young stroke and control group ( $t=1.79$ ,  $p=0.07$ ;  $\chi^2 =0.59$ ,  $p=0.44$ ;  $\chi^2$   
5  $=3.43$ ,  $p=0.33$ ); and between older stroke and control group ( $t=-1.52$ ,  $p=0.13$ ;  $\chi^2 =0.03$ ,  $p=0.86$ ;  
6  $\chi^2 =7.93$ ,  $p=0.16$ ). The groups were considered to be age-, gender- and education-similar for other  
7 comparison purposes.

### 20 21 **BAPM in younger and older stroke patients and healthy controls**

22  
23 Table 2 presents the scores of the younger and older groups of stroke patients and the  
24 corresponding healthy control groups on the three scores of the BAPM. Except for similar  
25 BAPM-BADL scores of the younger (mean = 1.14) and older control groups (mean = 1.11), the  
26 older groups had higher mean scores (range = 1.11-1.60) on the three scales indicating more  
27 frequent PM failure, irrespective of whether they were in the stroke (range = 1.22-1.60) or healthy  
28 control group (range=1.10-1.39). Similarly, stroke group had higher mean scores than healthy  
29 control group of the same age group. For all comparisons, the older stroke group had higher  
30 BAPM-BADL, BAPM-IADL, BAPM-TOTAL mean scores (1.49, 1.60, and 1.46 respectively)  
31 indicating more frequent PM failure compared to the individual means of the other three groups  
32 as well as the means of the three groups combined (1.15, 1.34, 1.18 respectively).  
33

55  
56  
57  
58  
59  
60 *Insert table 2 about here*

According to the results of one-way ANOVA, there were significant differences ( $p<0.001$ )  
in the BAPM-BADL score ( $F=10.57$ ), BAPM-IADL score ( $F=7.14$ ) and the BAPM-IADL score

1  
2  
3 (F=8.75) in the four groups (stroke-young and old; healthy control –young and old). Post hoc  
4  
5 analysis using Tukey’s test indicates that, for BAPM-BADL, the only significant difference was  
6  
7 between the older stroke group and the younger control group ( $p<0.001$ ). For BAPM-IADL, the  
8  
9 older stroke group reported more frequent PM failure than the younger stroke ( $p=0.029$ ), younger  
10  
11 control ( $p<0.001$ ) and older control ( $p<0.001$ ) groups. The BAPM-TOTAL score of the older  
12  
13 stroke group was also significantly different from the younger ( $p<0.001$ ) and older control  
14  
15 ( $p=0.01$ ) groups  
16  
17  
18  
19

### 20 21 22 **Comparison of PM ratings of stroke patients and relatives**

23  
24 Table 3 compared the patients’ score with their relatives for the younger and older stroke patient  
25  
26 groups and both groups combined. Relatives’ ratings of patients’ PM failures on the BAPM-  
27  
28 BADL scale were not significantly different from the patients’ ratings for both the younger and  
29  
30 older stroke group ( $t=0.66, p=0.55$ ;  $t= 0.86, p=0.39$  respectively). A significant difference was  
31  
32 found for BAPM-IADL score ( $t=2.88, p= 0.05$ ) for the older stroke group only, but not for the  
33  
34 younger stroke group ( $t=0.93, p=0.38$ ). The difference in BAPM-total score was not significant  
35  
36 for both the older ( $t=0.84, p= 0.42$ ) and the younger stroke ( $t=2.04, p=0.43$ ) groups. When the  
37  
38 older and younger stroke groups were combined into one sample there was a significant  
39  
40 difference between patient and relatives’ ratings for the BAPM-IADL score ( $t=2.56, p=0.01$ ), with  
41  
42 relatives rating the patient’s PM failure as more frequent.

### Correlations between PM, ADL and IADL

The correlations between BAPM-BADL and functional BADL, BAPM-IADL and functional IADL and total BAPM and total ADL functional assessments in the patient groups and relatives group are shown in table 4. There were significant negative relationships between BAPM-BADL and MBI scores ( $r=-0.40$ ,  $p<0.01$ ), BAPM-IADL and Lawton IADL scores ( $r=-0.27$ ,  $p<0.01$ ), as well as BAPM-total and Total ADL ( $r=-0.36$ ,  $p<0.01$ ) for the full sample of patients. For the older stroke group, moderate strength of relationship (i.e. value of  $r=0.3-0.5$ ) were found between BAPM-IADL and Lawton IADL scores ( $r=-0.24$ ,  $p<0.05$ ), between BAPM-BADL and MBI scores ( $r=-0.48$ ,  $p<0.01$ ), and between BAPM-total and Total ADL scores ( $r=-0.37$ ,  $p<0.01$ ). The correlation between the BAPM scores and the functional ADL scores was not significant for the younger stroke group. Furthermore, for the relatives' ratings there was no significant relationship between BAPM-IADL and functional IADL ( $r=-0.1$ ,  $p>0.05$ ), although the BAPM-BADL had a significant correlation with MBI score ( $r=-0.29$ ,  $p<0.05$ ), as did BAPM-Total and Total ADL functional score ( $r=-0.24$ ,  $p<0.05$ ).

### Discussion

This research studied the differences in self-report PM failures between older and younger people with stroke and their relatives explore the relationships between these PM failures and functional performance of stroke survivors. For the first aim of the study, we were able to differentiate the self-report PM failures of two stroke groups and with their corresponding age-similar control groups. Stroke patients' PM performance was poorer than controls which is consistent with

1  
2  
3 previous findings on brain injury [32]. The results also indicated that the older stroke group rated  
4 their PM failure as significantly more frequent than the younger stroke group. Literature has  
5 shown similar age-related decline in PM [33-35] and greater age-related deficits in event-based  
6 PM tasks (such as those items listed in the BAPM) that demand a higher control than automatic  
7 processing [36]. Age-related decline in PM may be associated with frontal lobe function [37] and  
8 partly explained by the associated lower performance of ongoing task in the older adults [38]. To  
9 date, there are a few studies showing PM abilities are reduced in stroke patients [22, 24, 39]. The  
10 present study may be another piece of evidence that stroke patients especially the older group face  
11 more difficulties performing PM tasks in general, and IADL tasks in particular.  
12

22  
23  
24  
25

26 The second aim was to compare self-report PM failures ratings from the perspective of the  
27 patient and their relative or caregiver. There were no significant differences between ratings of  
28 patients and relatives on the BAPM except for the BAPM-IADL ratings for the old stroke group  
29 and for both groups combined. This suggests a similarity in perceptions of PM performance  
30 between patients and their caregivers, and that overall patients are accurate in rating their PM  
31 performance, at least for PM tasks related to BADL. However, caregivers rated patient's PM  
32 failure on IADL tasks as being more frequent than rated by the patients themselves in the older  
33 stroke group. This might be due to self-rating bias or diminished self-awareness. Previous  
34 research in the traumatic brain injury population has also found that patients underestimate the  
35 frequency of their PM failure compared to relatives [40]. It cannot be concluded from the current  
36 study however that under-reporting of PM problems only occurs in the older stroke group as the  
37 non-significant results for the younger stroke group may reflect the small sample size (n=5) of  
38 patient-relative pairs in this group.

56  
57 The third aim was to investigate the relationship between PM and ADL functions. In line  
58  
59  
60

1  
2  
3 with previous findings in schizophrenia patients, it was expected that deficits of PM could  
4 possibly lead to disorganized ADL [40]. Evidence of a significant negative correlation between  
5 PM and functional ADL in schizophrenia patients has emerged in other studies [41-42]. The  
6 hypothesis that the PM of stroke patients on the BAPM would correlate with functional  
7 performance was supported. There was a medium negative relationship between PM impairment  
8 and BADL functional performance for the combined patient sample. **As a larger PM score**  
9 **represents worse performance while larger BADL means more function independence, poor PM is**  
10 **found to correlate with a decline in BADL performance.** Similar correlations were found for the  
11 older stroke group but not the young stroke group. This might be due to the smaller sample size.  
12

24  
25

26 The early findings of another study reported that PM was associated with IADL  
27 performance in an older age group [16]. PM dysfunction in both groups of stroke patients will  
28 affect their BADL and IADL performance [43]. In the present study, the relationship between PM  
29 performance and IADL performance was weaker, especially for the relative's rating where a very  
30 low correlation was found. PM failures on the IADL scale tend to relate to more non-routine PM  
31 activities than those on the BADL scale [26]. Possibly due to the non-routine and less frequent  
32 nature of these PM tasks, relatives may not have had the opportunity to observe the person with  
33 stroke performing the task or it may even be a task that the person is no longer expected to do  
34 since having their stroke (e.g., shopping, putting the garbage bin out). This could account for the  
35 weaker correlation on these items.  
36

46  
47  
48  
49

50 The findings of the present study may have several clinical implications. First, the results  
51 of the current study support that prospective memory deficits are widespread after stroke. **It will**  
52 **be a paradigm shift from doing routine clinical practice, which traditionally focuses on training**  
53 **retrospective memory or memory for the past events, to pay more attention to PM training. Stroke**  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 patients should also be trained to execute a delayed action which may be time- (e.g. attending a  
4  
5 medical appointment) or event-based (e.g. shopping when there is a sale). It is suggested that  
6  
7 possible problem areas in PM can be anticipated according to age range as well as stroke. This  
8  
9 avoids unrecognized PM difficulties that may restrict individuals' ability to engage in  
10  
11 rehabilitation strategies, and may shed light on treatment focus and preference for remedial or  
12  
13 compensatory activities. The treatment goal can be modified according to target PM areas  
14  
15 perceived by patients to be a problem in everyday life as these areas may be more prevalent and  
16  
17 demand more attention in rehabilitation. Second, family education is viewed as important as  
18  
19 differences in perception of were observed between relatives and stroke patients, especially for  
20  
21 items in the IADL area. Therapists should be aware of this difference in designing community  
22  
23 skills training while seeking the understanding and support from relatives. It may also be useful  
24  
25 to perform early screening using handy PM measures in identifying declining cognitive functions  
26  
27 which may hamper independence in IADL, and then BADL. Thus early education, prevention  
28  
29 and necessary interventions can be planned.  
30  
31  
32  
33  
34  
35  
36

37 One of the limitations of this study is its cross-sectional design. This has restricted  
38  
39 conclusions about the predictive value of PM to daily functional decline in BADL and IADL. In  
40  
41 this small sample study, we were not able to employ an additional clinical interview or  
42  
43 psychometric test of PM that would ensure a clinical diagnosis of PM deficit. As the BAPM is a  
44  
45 self-report questionnaire, objectivity of findings may be questioned and a performance-based PM  
46  
47 test may be more objective in ascertaining PM impairments in stroke patients. The Lawton IADL  
48  
49 has a similar problem because it also uses report from patients and relatives. Nevertheless, this  
50  
51 instrument has the benefit of asking for patients' own perceptions and those of relatives who are  
52  
53 familiar with the patients' performance in a real-world environment to rate the performance.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Another limitation of this study is that stroke patients may suffer from different degrees of RM  
4 impairment which was not well controlled. The possible heterogeneity across age within the two  
5 groups may also be a possible confounding variable, leading to unclear conclusions.  
6  
7  
8  
9

### 10 11 12 **Conclusions**

13  
14 This study revealed that self-report PM ratings related to BADL and IADL skills is impaired after  
15 a stroke in patients of different age ranges. They should be routinely assessed in clinical practice  
16 for early screening and monitoring throughout rehabilitation. In addition, the findings suggest that  
17 PM impairment is more pronounced for people who experienced strokes after the age of 55 years.  
18 The relationship between PM impairment and independence in ADL performance suggests that  
19 PM impairment is an important area to target in stroke rehabilitation.

**Table I. Descriptive statistics for younger and older stroke and control groups**

Characteristics	Younger stroke (n=29 )	Younger control (n=46 )	Older stroke (n=76 )	Older control (n= 66)
Gender				
Male	17 (58.60%)	15 (32.60%)	54 (71.70%)	46 (69.70%)
Female	12 (41.40%)	31(67.40%)	22 (28.90%)	20 (30.30%)
Age (years)				
Mean (SD)	49.28 (5.11)	45.48 (3.37)	67.07(6.92)	68.68 (5.24)
Range	36-55	28-55	56-94	60-81
Marital status				
Single	8 (27.60%)	32 (69.56%)	7 (9.20%)	9 (13.36%)
Married	18 (62.10%)	14 (30.44%)	56 (73.68%)	46 (69.69%)
Divorced	3 (10.30%)		5 (6.57%)	6 (9.09%)
Separated	0 (%)		2 (3.98%)	1 (1.52%)
Widowed	0 (%)		5 (6.57%)	4 (6.34%)
Educational level				
No formal education	0 (%)	0 (%)	4 (5.26%)	1 (7.57%)
Primary school	6 (20.70%)	13 (28.26%)	27 (35.52%)	19 (30.30%)
Secondary school	22 (75.90%)	31 (67.40%)	42 (55.28%)	44 (59.09%)
College	1 (3.40%)	0 (0%)	2 (2.63%)	1 (1.52%)
University or above	0 (0%)	2 (4.34%)	1 (1.31%)	1 (1.52%)
Post stroke period				
1 to 3 months	0 (%)		1 (1.33%)	
4-6 months	0 (%)		2 (2.63%)	
7 to 12 months	0 (%)		2 (2.63%)	
1 year to 2 years	2 (6.90%)		4 (5.26%)	
More than 2 years	27 (93.10%)		67 (88.15%)	
Types of hemiplegia				
Left side	10 (34.40%)		24 (31.58%)	
Right side	19 (65.50%)		32 (68.42%)	
History of illness				
Heart disease	2 (6.90%)		3 (5.93%)	
Hypertension	6 (20.70%)		26 (34.22%)	
Diabetes	2 (6.90%)		6 (7.89%)	
Others	12 (41.40%)		11 (14.47%)	
Heart disease & Hypertension	2 (6.9%)		12 (15.78%)	
Heart disease & Diabetes	1 (3.4%)		6 (7.89%)	
Hypertension & Diabetes	0 (0%)		3 (5.93%)	
Heart disease, Hypertension & Diabetes	0 (0%)		6 (7.89%)	
Period of received rehabilitation service				
Less than 3 months	5 (17.20%)			
3 to 6 months	5 (17.20%)			
7 to 9 months	6 (20.70%)			
9 months or above	13 (44.80%)			

**Table II. Analysis of variance of stroke and control groups (young and old) on BAPM-BADL, BAPM-IADL and BADL- TOTAL**

Group		Mean	SD	F	P
BAPM-BADL <sup>a</sup>	young stroke	1.22	0.33	10.57	<0.001
	old stroke	1.49	0.67		
	young control	1.14	0.14		
	old control	1.11	0.197		
BAPM-IADL <sup>b</sup>	young stroke	1.45	0.56	7.14	<0.001
	old stroke	1.60	0.64		
	young control	1.19	0.13		
	old control	1.39	0.30		
BAPM-TOTAL <sup>c</sup>	young stroke	1.27	0.40	8.75	<0.001
	old stroke	1.46	0.60		
	young control	1.10	0.11		
	old control	1.19	0.22		

<sup>a</sup> BAPM- BADL=the part of the Brief Assessment of Prospective Memory - relevant to basic activities of daily living.

<sup>b</sup> BAPM-IADL=the part of the Brief Assessment of Prospective Memory relevant to instrumental activities of daily living.

<sup>c</sup> BAPM-Total =the total score of the Brief Assessment of Prospective Memory

**Table III. Comparison of mean scores of patients' and relatives' ratings on BAPM-BADL, BAPM-IADL and BAPM-TOTAL**

Stroke age Group	Size	BAPM-BADL <sup>a</sup>			BAPM-IADL <sup>b</sup>			BAPM-TOTAL <sup>c</sup>		
		Mean (SD)	t	p	Mean (SD)	t	p	Mean (SD)	t	p
Younger stroke	5	1.17 (0.16)			1.22 (0.22)			1.20 (1.84)		
Younger stroke's relatives	5	1.30 (0.41)	-0.62	0.55	1.62 (0.93)	-0.93	0.38	1.46 (0.64)	-0.84	0.42
Older stroke	60	1.51 (0.72)			1.88 (0.74)			1.69 (0.68)		
Older stroke's relatives	60	1.39 (0.77)	0.86	0.39	1.46 (0.84)	2.88	0.05	1.43 (0.75)	2.04	0.43
All patient	65	1.38 (0.74)			1.47 (0.84)			1.43 (0.74)		
All relatives	65	1.48 (0.69)	0.78	0.43	1.83 (0.73)	2.56	0.01	1.66 (0.67)	1.83	0.06

<sup>a</sup> BAPM- BADL = the part of the Brief Assessment of Prospective Memory - relevant to basic activities of daily living.

<sup>b</sup> BAPM-IADL = the part of the Brief Assessment of Prospective Memory relevant to instrumental activities of daily living.

<sup>c</sup> BAPM-TOTAL = the total score of the Brief Assessment of Prospective Memory

**Table IV. Correlation between BAPM-BADL and functional BADL, BAPM-IADL and functional IADL and total BAPM and total ADL in patients and relatives group**

Measure	All Patients (n=105) r	Young Stroke (n=29) r	Old Stroke (n=75) r	Relatives (n=65) r
BAPM-BADL <sup>a</sup>	-0.40**	0.13	-0.48**	-0.29*
MBI <sup>b</sup>				
BAPM-IADL <sup>c</sup>	-0.27**	-0.23	-0.24*	-0.10
Lawton IADL <sup>d</sup>				
BAPM-Total <sup>e</sup>	-0.36**	-0.16	-0.37**	-0.24*
Total ADL <sup>f</sup>				

\*p < 0.05. \*\*p < 0.01

<sup>a</sup> BAPM-BADL = the part in the Brief Assessment of Prospective Memory relevant to basic activities of daily living.

<sup>b</sup> MBI = the scores of Modified Barthel Index.

<sup>c</sup> BAPM-IADL = the part in the Brief Assessment of Prospective Memory relevant to instrumental activities of daily living.

<sup>d</sup> Lawton IADL = the scores of Lawton instrumental activities of daily living Scale.

<sup>e</sup> BADL-Total = the total score of the Brief Assessment of Prospective Memory.

<sup>f</sup> Total ADL = the average scores of Modified Barthel Index and Lawton instrumental activities of daily living Scale.
